SALE and EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition No. 38.—  
"INLAND SCENERY WITH OR WITHOUT FIGURES." Latest day, July 25th.—Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in AMATEUR PHOTOGRAPHER Supplement, August 19th.)

WE have received an advanced copy of a pamphlet issued by the Photographic Convention, containing details of the excursions and the general programme, with the list of hotels and their tariffs.

The Convention will be opened on Monday, July 11th, at 6.30 p.m., with a reception by the President, Mr. Geo. Davison, in the hall of the Royal Scottish Geographical Society, Queen Street, Edinburgh. The presidential address will be delivered at 7.30 p.m., to be followed by a lantern exhibition. Tuesday will be devoted to an excursion to Melrose and Dryburgh. On Wednesday there will be the general meeting; the usual photographing of the Convention group in the morning, and the afternoon and evening to the reading of papers.

On Thursday there will be an excursion to St. Andrew's and Dunfermline, and in the evening more papers. On Friday excursions to Dalmeny and Cramond Bridge, Roslin and Hawthornden, and a dinner and smoking concert in the evening. Saturday sees the close of the gathering with a council meeting.

The papers to be read are as follows:—

"Individuality in Photography," by H. P. Robinson.

"The Art of Photography in Relation to Painting," by A. Burchett.

"Amateur Photography in America," by Miss Catherine Weed Barnes.

"Orthochromatic Photography," by C. H. Bothamley.

"Photography in Relation to Medical Record and Demonstration," by A. Pringle.

"On the Training of Photographers," by E. A. Howard Farmer. A paper from W. R. Burton.

"The Use of the Colour Screen in Landscape Photography," by C. L. Mitchell, M.D.

"Direct Silhouette Portraiture" (with lantern illustration), by J. Cox Cox.

"How to Look at Photographs," by F. M. Sutcliffe.

MR. POPHAM, of South Shields, sends us the following letter with regard to our remarks on his print in our last issue:—

"Allow me to again state that my print was a faithful representation of the sunrise of March 29th, at 6 a.m. The presence of two eye-witnesses, and the impressions of two negatives, are to my mind undoubted testimony against the declaration of one who admits he was not at South Shields on March 29th, at 6 a.m. The knowledge of having one's print rejected in the first round is easily accounted for by the prejudice which exists against sunrise effects; for I find there were more sent in than mine. Might I ask you if it is a photographic sin to attempt to photograph a sunrise? Surely, if it is, photography has poor claims to become a fine art."

As Mr. Popham still maintains that it is a faithful representation of a sunrise, we can only say it was a very curious

one and well worth photographing as an unusual phenomenon. As to the print being thrown out from prejudice, we may assure our correspondent that two judges are hardly likely to throw a print out for this reason in our presence. This is bringing an unwarranted and insulting charge against the good faith of our judges and ourselves.

It is not a photographic sin to photograph a sunrise, but it is a photographic sin to make the print lie by over-printing. Our own impression, from an examination of the print, is that the negative was developed with too much reducing agent and bromide, and therefore to obtain detail in the white clouds the print was over-printed, and thus the true rendering of the scene destroyed.

A CORRESPONDENT writes suggesting a slight alteration with regard to our competitions, viz., to the effect that we should limit our competitions to one particular plate, one lens, one kind of printing-paper, giving each a turn. As all announcements had been made with regard to this year's competitions, we cannot see our way clear to institute this change this year, but we think the idea well worth considering for next year.

The 1892 AMATEUR PHOTOGRAPHER Annual Lantern Slide Competition will close on September 30th, and the following are the classes and prizes:—

CLASS I. LANDSCAPE, SEASCAPE, AND RIVER SCENERY, with or without figures.

First Prize .. .. .	Gold Medal.
Second Prize .. .. .	Silver Medal.
Third Prize .. .. .	Bronze Medal.

CLASS II. PORTRAITURE AND FIGURE STUDIES.

First Prize .. .. .	Gold Medal.
Second Prize .. .. .	Silver Medal.
Third Prize .. .. .	Bronze Medal.

CLASS III. ARCHITECTURE, interior or exterior.

First Prize .. .. .	Gold Medal.
Second Prize .. .. .	Silver Medal.
Third Prize .. .. .	Bronze Medal.

CLASS IV. INSTANTANEOUS WORK, limited to slides from 5 by 4 negatives and under.

First Prize .. .. .	Gold Medal.
Second Prize .. .. .	Silver medal.
Third Prize .. .. .	Bronze Medal.

Certificates will also be placed at the disposal of the judges.

Entry forms and conditions, etc., will be ready in the course of the next fortnight, and may be obtained on forwarding stamped directed envelope.

THE photographic societies in the Metropolitan district south of the Thames propose to hold an exhibition in November, and the Committee of the South London Photographic Society offer for competition by members of the South Metropolitan Photographic Societies, at their Exhibition, to be held in November, 1892, the following medals:—Silver medal for the best photograph shown (irrespective of size); bronze medal for the second best ditto; silver medal for the best set of six lantern slides; bronze medal for the second best ditto. Entrance fee payable only by non-members of the South London Photographic Society, 2s. 6d. each competitor.

#### RULES FOR COMPETITION.

1. The term "Photograph" used in these rules shall include photographic productions of all kinds.

2. Photographs for competition at the Exhibition shall be from negatives taken since the date the competitor was elected a *bona fide* member of one of the South Metropolitan Photographic Societies.

3. Not less than six photographs shall constitute an exhibit.

4. Exhibits for competition should bear the title and name of the competitor on the front, lantern slides and transparencies excepted. Names of competitors will be covered during judging.

5. Oxford frames will be excluded.

6. Lantern slides must be 3½ inches square, properly mounted and marked, so that the name of the subject or title shall be seen at the top on the face of the slide when looked at in its correct position.

7. The Committee shall have power to reject any exhibit which may appear to them unsuitable or in contravention of the rules.

8. The judges shall be appointed by the Committee.

9. The decision of the judges to be final.

10. The term "South Metropolitan Photographic Society" includes any Photographic Society whose meeting place is situated within the South London Postal District.

11. Any member of the South London Photographic Society who is successful in obtaining an award shall present a copy of the photograph to the society's album.

12. In the classes open to members of the South London Photographic Society only photographs from negatives taken since the competitor was elected a member of the society, are eligible, provided that the same have not been exhibited for competition at any of the society's previous exhibitions, and no member shall receive more than one award in those classes.

13. The Committee will arrange for every care to be taken of the photographs, but they will not hold themselves responsible for any loss or damage which may occur to them. Ten per cent. commission will be payable to the society on the price of all photographs sold during the exhibition.

The date and place of exhibition will be announced shortly. Entry forms can be obtained from the Secretaries of any of the South Metropolitan Photographic Societies, or of the Hon. Secretary, Chas. H. Oakden, 51, Melbourne Grove, East Dulwich, S.E.

We wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

#### HOLIDAYS WITH THE CAMERA.

To many of our readers the summer holidays are the only period in the year at which they can devote as much time as they like in the daytime to photography, so that in many cases the deciding question becomes where to go, so that renewed health may be obtained with also a renewed stock of negatives.

To some of us the claims of our family require to be considered, and the sea-side, if chosen, as it is by many, will give us numerous chances of beach scenes, clouds, and shipping. We may, once for all, dismiss beach scenes, and say that they are, as a rule, extremely disappointing, and bear a striking resemblance one to another. It is true that to the hand-camera man they present great opportunities to obtain snap-shots, but one gets very tired of the interminable children paddling, or building sand-castles, etc., and it is rare to see any real artistic merit in them.

High water is, as a rule, not the best time to make pictures. Choose low tide, especially at any place where fishing is carried on; and many a charming picture may be obtained by judicious selection—the faint ripples, the ripple-

marked sand, and the reflection of a boat are all of value, and, perhaps, an attendant fisherman or two may lend life and interest to the print.

In all cases, however, avoid too much posing. And on this point we can recommend the suggestion made by one of our contributors, Mr. J. A. Hodges, who showed us some charming results obtained this month at the sea-side. On examining his negatives we were much struck by the absolute unconsciousness of the fishermen in most of them, and he said, "Yes; in most cases they were ignorant of my taking them, as I used only one combination of my rectilinear, and, therefore, did not have to get so near them." In all work of this kind it is advisable to use one combination of a doublet, or else a long-focus lens, and we may state that it is worth while purchasing a long-focus single lens for this purpose. In using a rectilinear, the usual advice is to unscrew the front combination and use the back only; but many cameras will not rack out sufficiently far to allow this to be done. Equally good results can be obtained by unscrewing the back combination, and using the front *in situ*, the extra length of tube being quite sufficient to enable the lens to be thus used. Using half a lens in this manner, it must not be forgotten that as the equivalent focus is doubled the aperture of the diaphragm is halved, and therefore the exposure increased to four times.

Another question on which doubtless many of our readers will look for help is with regard to shutters. "What is the best instantaneous shutter for seaside work?" someone will ask. Well, for ordinary work, a shutter which does not work quicker than 1-30th of a second will be quite rapid enough, and Mr. Hodges had a note on this very subject, in our issue of June 17th, page 467, and certainly from an examination of his negatives they fully bear out this recommendation. It is true that we may sometimes require a shutter which should work at a quicker speed, for instance, in taking a shot at a yacht coming in on a stiff breeze, with every stitch of canvas set, then perhaps 1-100th of a second may be required, but we shall want her heeling over, and throwing up some spray, or else we shall get no idea of motion. This reminds us, too, how careless some amateurs are with regard to instantaneous work. Many will take up their position regardless of the position of the sun. Last year we were at the sea-side and we wanted to take a small yacht coming in on the top of the tide, with a fair breeze, and the only place easily getatable was the end of a small pier; when we got there we found we should be on the shadow side of the boat, so had to walk two hundred yards, take a boat across the river mouth, climb over some rough ground and up some wooden piles at some risk, and then managed to get a good result by lying flat on the top of the piles, and holding the camera firmly in front of us. Always be careful that in very quick work you do not get on the shadow side of the object to be taken.

The question of plates is another crux. A query often asked is, "Are So-and-so's ordinary plates quick enough for sea-side work?" Probably they are quick enough, and yet we venture to think they are too slow. The light, as a rule, at the sea-side is always more actinic than inland, where we have smoke, etc., to take off the power, and then there is so much more sky in our pictures, as a rule, and fewer heavy shadows that one can use a slower plate if thought desirable. But is it desirable? We think not; we should prefer a rapid plate, and, if necessary, stop down our lens, or use a more rapid shutter to compensate for the increased sensitiveness. The greater sensitiveness is a power which it is as well to have in reserve, we need not use it unless we like, but still it is there if we want it.

Having considered these points, the natural sequence is

How shall we develop our exposed plates? If they have been exposed on shipping, or any subject in which fine portions like cordage, ropes, etc., appear against a bright sky, then it is advisable to apply a developer of full strength so as to avoid what is called halation, which in many cases is sideways extension, or creeping of the deposition of the metallic image, in consequence of slow development. For this class of work, plain pyro and ammonia is still our favourite. Hydroquinone gives rise too often to chalkiness in the high lights, and eikonogen is less under control, though far more preferable than hydroquinone and more preferable than pyro, sulphite, and the fixed alkalies, potash, or soda. If a plain pyro developer with full strength ammonia be used, the negatives will develop up quickly without undue contrast, and more often than not with clouds showing, if any were about at the time of exposure. Thin, soft, and delicate negatives are far preferable to denser ones, and we have a strong leaning to yellow negatives, that is negatives developed with plain pyro, uncleaned and fixed in a neutral and not an acid fixing bath. Yellow negatives are far better printers than black and white ones, or, as the Germans say, the colour of the image "deckt gut," a comprehensive term, and for which we have in English no equivalent.

Our final note must be as to clouds. At least a dozen plates should be devoted to studies of the clouds in the daytime, and if any energy is inherent, a few sunrises will well repay the trouble of getting up, but one must be careful not to spoil these by over-printing, as so often seen in our competitions. Don't descend to clap-trap in photography. By clap-trap we mean under-exposing plates, over-printing in order to get startling nocturnes in black and white, which though effective at first sight, will on further examination at once reveal all false values and results utterly untrue to nature. Photography, unfortunately, cannot help lying in some particulars, but we need not make it lie worse than ever.

## Letters to the Editor.

### THE NEW CLASP.

SIR,—With regard to your intention to award an extra clasp to the medals (or ribbons) of past prize-winners, will you permit me to express my opinion upon it. I consider the idea both novel and excellent. I have your Monthly Bronze Medal and two of your certificates, and as hitherto I have been unable to obtain the Monthly Silver Medal, I will hail with pleasure any extra clasp I should be lucky enough to obtain. It will certainly be almost as good as a medal. Hope some of your other prize-winners will express their views. I shall try for one of these new decorations in next month's competition, but of course would prefer a Silver!—Yours truly,  
PRIZE-WINNER.

\* \* \* \*

### HINTS TO BEGINNERS.

SIR,—Absence from home has prevented my seeing your issue of the 3rd inst., otherwise I would have replied sooner to Mr. Forret's kind criticism of my paper under the above heading. As a "mere amateur" I am only too glad to learn all I can; and, as Mr. Forret considers some of my statements as rather misleading, I shall be very glad if he will point them out, as, not only I do not wish to lead others astray, but it is not at all improbable that I may, myself, have been in the wrong track; consequently, I look forward with interest to that gentleman's next communication.

As regards the point he especially criticises, his second construction correctly defines what I wished to express, and I am very sorry if my assertion was at all indefinite. I wished to impress on amateurs the necessity of filtering the hypo solution for two reasons—the unequal density of a long-standing solution, and the very frequent occurrence of foreign matter among the crystals of hypo. I am glad to learn that *photographically* this unequal density is of little importance as far as regards hypo, but I have

had an unpleasant experience as regards chloride of gold; when using the last of a solution of 1 gr. to the dram, my prints toned with such violent rapidity that half of the batch was spoilt, and this, I was told by the dealer who supplied the gold, was in consequence of the last of the solution, which had stood some time, being much more dense than that previously used—than the upper layers, in fact. With regard to the expression “large handful,” that referred to preparing the fixing solution for prints, and which I acknowledged at the time to be somewhat a “rough and ready” means of compounding the bath. However, the “proof of the pudding is in the eating,” and I have three prints which were inadvertently left in a damp outhouse last winter, two by professionals and one of my own doing; one of the professionals’ work was extremely discoloured, the other was very much spotted, while my work was not harmed in the least, except that the mount was a little soiled. I shall, if you wish it, be most happy to leave them with you for Mr. Forret’s inspection when I next am in London.—Yours, etc., NOVOCASTRIENSIS.

[Our correspondent has called upon us and left some prints with us, amongst them one only of his which shows one small patch of fading, but this may be due to the mounting board.—Ed.]

\* \* \* \*

### THE BLISTER FIEND.

SIR,—Allow me to protest against the treatment proposed by your correspondent “John Browning,” for the prevention of blisters on silver prints. I have tried the experiment, with the result that I have twenty prints which can claim no better place than the waste-paper basket. The prints would lead one to think they were all printed from flat negatives, which is not the case, presenting a washed-out appearance, and some of them came out of the toning bath with untuned spots and patches over them, a thing which I very rarely experience, as I am most particular about keeping my prints away from anything that may convey grease to their surface.—Yours, etc., P.

\* \* \* \*

### UNIVERSAL HAND CAMERA.

SIR,—In Major Bruno’s articles on a universal hand camera, at p. 489 of your issue of June 24th, he tells his readers how to construct a finder with a bi-concave lens and a mirror (at 45°) to be used by looking down through the top of it.

But surely the image, as viewed at G fig. 10 will not be, as he tells us, “the right way up,” unless the operator turns his back towards the view taken.

This might be useful with inquisitive crowds, as has, before now, been suggested.

As to the greater brightness of the image, and that considerable advantage over the ordinary ground-glass affair, with bi-convex lens and mirror, there can be no doubt, and I should be very grateful to the author of these articles if he can modify his arrangement so as really to see the view “the right way up” when looking down on G.

As he has it arranged at present, the view will be inverted, as on the ground-glass of an ordinary camera.

A second mirror could, of course, be easily arranged over his sunk finder, so as to give an erect image when the operator looks directly towards the view; but as that second mirror would have to project above the top of the camera, it would be simpler to put the bi-concave lens there; hinged to fold down flush, and to look through it in a horizontal direction as in the common bi-concave finders, without any mirrors at all.

But neither of these two latter methods admits of using a sunk finder by looking down on it, which, for many purposes, is the most convenient position.—Yours, etc., H. E. H.

### HOW LONG WILL DRY PLATES KEEP?

SIR,—Prior to Whitsuntide of 1867 (twenty-five years since) I purchased from the Liverpool Dry Plate Co. a stock of their collodio bromide plates to take with me on a visit to the English lakes. Having exposed a number of them with more or less success, on my return home I had a few left, and not doing anything in photography for some time after they got put away, and lost sight of. Since then they have been tumbled about in three houses, from basement to attic or lumber room, and coming upon them the other day I thought I would expose a plate and see if they had any life left in them.

I gave a long exposure on a view from an upper window and forgetting the exact mode of development recommended at the

time for them, I used pyro and ammonia, and to my surprise produced a rather unsightly, but fair printing negative. I enclose you the negative and a print from it for your inspection as I think it may be interesting to you and the readers of the AMATEUR PHOTOGRAPHER.

The Liverpool dry plates were about the first commercial plates put on the market, the worker in dry-plate photography having prior to their advent to prepare his plates himself from the many and varied formula from time to time published.

The Liverpool plates used to take about three times the exposure of wet plates under the most favourable circumstances, and for masses of dark green woods took often five or six minutes. The film had to be varnished round the edge to prevent blistering and stripping off during development. They were backed with a red coloured water paint to prevent halation, and, of course, this had first to be carefully washed off prior to development.—Yours, etc., J. H. JACKSON.

[The print sent by our correspondent is far superior to many that we get in our competitions from the modern dry plates, and speaks well for the keeping power of the plates.—Ed.]

## Apparatus.

### THE “SANDELL” PLATE.

R. W. Thomas and Co., of 10, Pall Mall, London, W., have sent us a sample of the plates they have introduced under the above-named title. The plates are coated with two or more films of emulsions of different degrees of sensitiveness, the idea being expressed by the makers as follows:—“It will be readily perceived that their construction, whilst perfectly obstructing the passage of reflected light from the glass or support to the most sensitive film, thus preventing halation, effects another object, and this is an important one—it allows a latitude in exposure altogether impossible for any single film, for one is able to give an exposure in which the sensitive salt in the upper film or films is absolutely solarised or reversed, whilst a perfect image may still be secured in the lower strata.”

These plates have certainly given us some good results under very trying conditions, but not when developed in the usual manner. For instance, when exposing on a brilliant sun-lit view for four times the normal exposure, we found on applying a developer of full strength pyro and ammonia that the negative was flat and foggy, whereas another plate exposed on the same view under identical conditions gave when developed with a well restrained pyro developer weak in ammonia (one-fourth of the normal quantity) a brilliant plucky negative. The makers recommend that “when the image rushes up and the shadows become all obscured, development may still be continued with the normal developer; . . . in this case, after fixing, it will be found probably necessary to clear the negative,” and suggest Howard Farmer’s ferrideyanide reducer. In our hands, however, this has not given us such good results as by the reduction of accelerator.

With regard to halation, we think the plates certainly score as severe trials on opal globes surrounding a bright gas flame gave us no halation with an exposure which was four times longer than was required to produce marked halation on their ordinary plates. In photographing barges also on the Thames we were able to obtain all the cordage most distinctly and clearly outlined with no trace of halation with two seconds’ exposure in bright sunlight against a very bright sky. In cases where halation is to be expected these plates should prove useful, and it is to be regretted that their price is so high, viz.:—

Quarter-plates	..	..	..	2s. 3d. and 3s.
Half-plates	..	..	..	4s. 9d. „ 7s.
Whole-plates	..	..	..	8s. 9d. „ 13s.

The plates are made in two kinds, “General” for ordinary work and “Especial” for very trying subjects. The speed of the plates is said to be “Sens No. 28° W,” but in our hands they do not seem to be quite so rapid as some other plates, not even so sensitive as Thomas’ Cyclist. But on this point our experiments do not enable us to speak with any certainty.

### THE EASTMAN GELATINO-CHLORIDE PAPER

The Eastman Photographic Materials Company, of 115, Oxford Street, W., have introduced a new form of gelatino-chloride paper, which they claim to be the result of “experiments

which have been conducted with the greatest possible care with a view of eliminating some of the difficulties and uncertainties which have heretofore been absolutely inseparable from the manufacture of printing-out papers." And judging from the samples sent us which we have tried during this last week the paper is of first-rate quality and singularly free from blemishes and defects. It is as rapid as any chloride paper in the market, and there seems to be rather less loss of depth than usual. With the usual formulæ it works excellently. The special toning bath recommended is as follows:—

#### COMBINED TONING AND FIXING BATH.

##### No. 1—ALUM AND HYPO SOLUTION.

Hypsulphite of soda ... ..	8 oz.
Alum ... ..	6 "
Water ... ..	64 "

When dissolved add to above 3 oz. carbonate of soda, dissolved in 8 oz. of water. (This must be added very carefully on account of the effervescence which takes place.)

Allow to stand twenty-four hours, then decant the clear liquid.

##### No. 2—GOLD SOLUTION.

Chloride of gold ... ..	15 gr.
Acetate of lead (sugar of lead) ... ..	64 "
Water ... ..	8 oz.

To make the toning bath:

Take of No. 1 solution ... ..	8 oz.
Take of No. 2 solution ... ..	1 "

After printing immerse without previously washing in the above toning bath until the desired tone is obtained.

The above solutions will keep any length of time.

When toned transfer the prints to the washing-tray, giving at least one hour and a half's thorough washing in several changes of water.

Should any other formula be used for toning, the prints, when toned, must be washed in two or three changes of water, and then fixed in a bath of hyposulphite of soda of the following strength:—

Hypsulphite of soda ... ..	3 oz.
Water ... ..	1 pint.

A special feature and a very convenient one is the packing of the paper cut to the regulation sizes in 1s. packets, so that no matter what size negative is used one can always obtain a shilling's worth of this paper, which will be of great service to those of our readers who wish to obtain a few prints without investing in a lot of uncut sheets. It may also be obtained in full-size sheets 24½ by 17; price 15s. per quire.

#### THE VARDEN STAND.

Mr. E. Varden, of Boundary Road, Notting Hill, W., has submitted for our notice one of his tripod stands. It is extremely light and rigid, and has sliding legs adjustable to any height or uneven ground. The head is mahogany, covered with cloth, and at the reasonable price of 12s. 6d., the stand should find many friends.

#### POWELL'S COMPRESSED TONING BATHS.

T. H. Powell, of 116, Denmark Hill, London, S.E., has forwarded us a sample of his compressed gold and platinum toning baths. They have given us very fine tones on albumen and gelatino-chloride prints, and judging from the time we have had them under our notice, they possess, when dissolved ready for use, good keeping powers. Many of our readers will warmly welcome this novelty, as the contents of a tube (two of which are sold for 1s.), have merely to be dissolved in half a pint of water to be immediately ready for use. We have toned sixteen half-plate prints in one bath without exhausting the gold.

## Catalogues.

*Fallowfield's Photographic Annual.* Price 1s.

Jonathan Fallowfield, of 146, Charing Cross Road, has sent us a copy of his encyclopedic price list, which this year runs up to 592 pages. Every requisite that the most enthusiastic worker may require is here quoted for, and in many cases illustrated. The very latest novelties are included, and the work is an absolutely necessary reference book for any amateur.

## Photographic Procedure.

By E. J. WALL,

Author of the "Dictionary of Photography."

#### SECTION V.

#### THE SENSITIVE MEDIUM AND ITS SUPPORT.

(Continued from p. 451.)

In 1869 Taylor (*Photographic News*, 1889, p. 19), suggested the use of a photometer, which has also been used as a sensitometer, consisting of a small box containing ten tubes, one end of which was bored with a certain number of holes, viz., 3, 4, 5, 6, 8, 10, 13, 16, 20, and 25, the increasing number of holes, admitting, of course, an increasing amount of light, which acted on the sensitive surface.

FIG. 123.

FIG. 124.

In 1881, Mucklow and Spurge introduced their sensitometer, which is shown in figs. 123, 124, and 125, and it consists of a box with chambers, one end of which is closed by an opaque plate perforated by holes of given diameters, a numbered plate is at the other, and behind this number tablet, a sensitive plate is exposed, and on development would show a certain number, which can be used for comparison with that furnished by a different plate. The intensity of the light being proportional to the square of the diameter of the holes.

1	2	3	4	5
10	9	8	7	6
11	12	13	14	15
20	19	18	17	16
21	22	23	24	25
30	29	28	27	26

FIG. 125.

At the Camera Club Conference held in March last, an improvement on the above instrument was suggested by Mr. J. B. Spurge, which "consists in the re-arrangement of the chambers which now partake somewhat of the nature of magic squares:—

#### DIAGRAM OF INSTRUMENT.

Areas Ratios	31 3.7	39 2.52	50 2	63 1.6	79 1.26	100 1	Largest Aperture.
	7.8 12.7	9.9 10	12.5 8	15 6.35	19 5.03	25 4	
	1.96 50	2.48 40	3.12 32	3.93 25	4.96 20	6.25 16	
Smallest Aperture.	.492 202	.620 160	.781 128	.984 101	1.24 80	1.56 64	

These considered vertically downwards receive quarter the exposure of those immediately above, and correspondingly four times of those below. When diagonally considered, those upwards and towards the right receive

approximately five times, and conversely when downwards and to the left, 1-5th the exposure. Diagonally upwards, and to the left approximately three times, and downwards towards the right, 1-3rd. A ready means is now afforded of seeing at a glance the effect of exposures, all bearing a geometric relationship, and of four different ratios to one another. This upon one quarter-plate, thus rendering it a portable and exact instrument for general work.

FIG. 126.

Dr. Vogel uses a sensitometer constructed much after Taylor's, and as shown in fig. 126, consists of two chambers placed side by side with a movable cover. To use this, two plates, the sensitiveness of which it is desired to compare are placed side by side in the sensitometer, and the same exposed to a screen of white paper, illuminated by skylight, at some distance from an open window as shown in fig. 127.

FIG. 127.

F being the window, S the screen, and P the plates in the sensitometer, which is fastened at a distance of 1 metre (39.37 in.) from the screen, which measures 40 cm. square (16 sq. in.) as in fig. 128.

FIG. 128.

The front of the sensitometer is pierced, as will be seen with two-sets of holes from one to twenty-four, and a numbered tablet is just in front of the sensitive plate, and the exposed plates are developed and fixed together. The sensitiveness of the plates is directly proportional to the different numbers; for instance, a plate showing twelve is twice as sensitive as one showing six.

(To be continued.)

## Elementary Photography.

BY JOHN A. HODGES.

### CHAPTER XXII.

#### ISOCROMATIC OR COLOUR-SENSITIVE PHOTOGRAPHY.

Isochromatic Plates—Their Advantages—How Prepared—Dipping Process—Emulsion Process—Tailfer's Patent—Edwards' Isochromatic Plates—Further Improvements Desirable—Special Advantages—Necessity for Manipulating in Ruby Light—Further Precautions—Development—The Use of "Screens"—A Useful Experiment—Photographing Skies—Length of Exposure with Screens.

It will soon become apparent, to even the most unobservant reader, that photography does not with even approximate accuracy reproduce the true gradations of light and shade, nor render in monochrome colours according to their proper value. Ordinary plates are almost insensitive to red, scarcely more so to orange and yellow, and reproduce most greens badly, at the same time being unduly sensitive to blue and violet. Chemists, recognising this shortcoming of photography, have long turned their attention to the production of plates which shall be more equally sensitive to the various colours of the spectrum, and the result of their investigations has been the introduction of what are known as isochromatic or orthochromatic plates. The terms are practically synonymous, and signify equal or true rendering of colour. It would be beyond the scope of a practical and elementary guide-book to go into the history of the process here, or to describe its nature, except in the briefest possible manner. Fortunately for the amateur, isochromatic plates are now an article of commerce, therefore it will not be necessary for the reader, from a practical point of view, to trouble himself with any details of their manufacture. They may be produced in two ways, first, by dipping, or bathing, ordinary plates in a solution of erythrosine, one of the very numerous coal-tar derivatives; plates so prepared, however, will not retain their keeping qualities, and therefore must be used directly after being prepared. The alternative method is due to M. Tailfer, a Frenchman, and is the subject of a patent; and Mr. Edwards's isochromatic plates, produced under licence by this process, have acquired a well-deserved reputation for their uniform reliability and excellence. I have used isochromatic plates from the time of their introduction, and for most purposes I consider they are far superior to ordinary plates. Photographers generally, however, have until recently been slow to adopt them, or to recognise their advantages; one probable reason for this I shall refer to later. So very much better are they than ordinary plates that I have not the least hesitation in expressing the opinion that the day is not very far distant when colour-sensitive plates will be almost exclusively used, and the fact that quite recently one of the largest firms of plate-makers have considered it worth their while, as a business speculation, to purchase the right of making such plates from Messrs. Edwards, is strong evidence of the correctness of the assertion. Finality, however, in the preparation of colour-sensitive plates is very far from being reached, and several gentlemen who have devoted much attention to the investigation of the subject are still hard at work in this direction.

From a practical point of view isochromatic plates may be regarded as superior to ordinary plates for the following special purposes: copying oil or water-colour paintings and coloured diagrams, landscape work generally in which green or yellowish green is the prevailing colour, and more particularly when the foliage has assumed the brown and yellow tints of autumn; they also render clouds better and more truthfully than do ordinary plates, while portraits taken upon them require less work from the retoucher's pencil.

# W. WATSON & SONS, 313, HIGH HOLBORN, LONDON,

HAVE RECENTLY BEEN AWARDED

At the **AMSTERDAM** PHOTO EXHIBITION, 1891—THE **MEDAL OF THE SOCIETY**

At the **GLASGOW** PHOTO EXHIBITION, 1891—THE **MEDAL OF THE SOCIETY.**

At the **ANTWERP** INTERNATIONAL MICROSCOPIC EXHIBITION, 1891—TWO DIPLOMAS OF HONOUR  
(Degree above Gold Medals).

At **BUDAPESTH**—THE **GOLD MEDAL OF THE PHOTOGRAPHIC SOCIETY.**

Making 27 awards for the excellence of their Instruments, including Paris Universal Exhibition, 1889 (2 Gold), London, Liverpool Melbourne, etc.

W. WATSON & SONS believe they are the largest Manufacturers of High-class Photographic Instruments in Europe, and intending Purchasers can be allowed at any time to inspect their Steam Factories, which are close to their Warehouse, and judge for themselves as to the quality of Material used and the care bestowed on the Manufacture of their Goods, which W. & S. are confident is elsewhere unequalled. *Testimonials as to the efficiency of their Instruments are received almost daily.*

## Watson's "Acme" Camera.

Unsurpassed for Outdoor use.

## Watson's "Premier" Cameras.

For Professional use, *Indoor or Out.*

## Watson's Studio Cameras, Tripods, Enlarging Lanterns, etc.

## Sensitized Albumenized Paper.

The Best White or Rose. Per quire, 13s.; half quire, 6s. 6d.; quarter quire, 3s. 6d. Single sheet, 10d., post free.

AN ILLUSTRATED CATALOGUE OF CAMERAS, LENSES, AND APPARATUS SENT FREE TO ANY ADDRESS ON APPLICATION. Established 1837.

— AND AT MELBOURNE, AUSTRALIA—251, SWANSTON STREET. —

STEAM FACTORIES: 9, 10, 11, 16, and 17, FULWOOD'S RENTS, HOLBORN.

## Watson's "Detective" Hand Camera.

## Watson's Rapid Rectilinear Lenses.

## Watson's Wide Angle and Single Landscape Lenses.

All Cameras and Lenses may now, at an advanced cost, have the Metal parts made in Aluminium.

## Sensitized Matt-Surface Paper.

Exceedingly popular. Yields most artistic results. Per quire, 13s. half quire, 6s. 6d.; quarter quire, 3s. 6d. Single sheet, 10d., post free.

## Wratten & Wainwright's CELEBRATED

# "LONDON" PLATES,

"ORDINARY" (15°). For Landscapes, Copying, and Transparencies.

"INSTANTANEOUS" (19°). For Studio and General Work.

"DROP-SHUTTER SPECIAL (24°). For Dull Weather and Hand Cameras. The most rapid Plate made.

Have been manufactured continuously for fifteen years, and have never yet been approached in quality. They are recognised by the most competent authorities as the standard by which all other Plates are judged. These Plates are indispensable for the production of Exhibition Pictures. More High Class Medals have been secured by results on the "London" Plates than all others combined.

## Wratten & Wainwright's SENSITIZED PAPER

HAS THE LARGEST SALE AND HIGHEST REPUTATION, KEEPS WELL,  
TONES EASILY, AND DOES NOT BLISTER.

Post Free—per Quire, 13/6; Half-quire, 7/-; Quarter-quire, 4/-; 3 Sheets, 2/3; Sample Sheet 10d.  
Cut Sizes, 1/- per Quire extra.

The one drawback to the use of isochromatic plates, if such it can be said to be, lies in the fact that they can only be safely manipulated in light of a *deep ruby colour*, and to a disregard of this precaution a good many failures are readily attributable. It needs very little reflection to demonstrate that a plate which is capable of accurately rendering orange and yellow cannot safely be manipulated in a light of that hue. Ruby light only, and that of a proper character, should be employed. It is better not to expose the plates unnecessarily to even ruby light, and in filling the dark-slides it is well to get as far from the light as possible. During development a light wood or cardboard cover should be placed over the dish until the image is well out.

In regard to the actual development of isochromatic plates, their treatment does not essentially differ from that applicable to ordinary plates, only that with those of Edwards's make it is very easy to secure density, so that with subjects showing much contrast less pyro is necessary.

The makers, in their instructions, advise the use of the fixed alkalis, either the carbonates of potash or soda, rather than liquor ammonia, inasmuch as if an excess of the latter be used fog would probably result. The same, however, applies, though perhaps in a less degree, to ordinary plates, and I invariably employ ammonia without meeting with any ill-effects. Hydroquinone is recommended by some workers, but, owing to its tendency to give negatives of a chalky nature, I seldom use it. There is, however, less chance of fog when employing it than when the pyro and ammonia developer is used. There is one precaution which after what has been said will probably be obvious, and that is that when examining the negative for detail and density during the progress of development it should not be exposed for long, or held too near the dark-room window or lamp, as the plates are, to some extent, sensitive to even the ruby light of the dark-room.

In order to obtain the full advantages of colour-sensitive plates it is necessary to use a "screen." This is a disc of yellow glass, varying in depth of tint from a very pale lemon colour to a much darker yellow. It may be obtained to fit inside the lens mounts, or behind the lens itself. The object of using a "screen" is to cut off some of the blue and violet rays, which have too great an effect upon even an isochromatic plate when used without a screen.

The chief advantage of the screen is found when copying paintings. Its use is then invaluable, and it would be both interesting and instructive to the reader if he were to make three copies of a brilliantly coloured painting or chromolithograph; the one on an ordinary plate, the next two on isochromatic plates with and without a screen. If full justice has been done to each negative, a most striking difference in quality will be apparent, the isochromatic plate *used with a screen* giving by far the most truthful rendering of the subject.

For photographing cloud and sunset effects isochromatic plates give results distinctly better than those obtainable on ordinary ones. The finest effects of this kind are usually obtainable in the spring and autumn, when, as a rule, stormy and strongly-marked skies prevail. From about an hour before to the period of actual sunset is, perhaps, the best time to get effects of this character. A suitable standpoint having been selected (if the negatives are to be used for double printing, a low horizon should be chosen) the camera is directed towards the sun itself. A moment when it is obscured or partially obscured by a cloud should be chosen for the exposure, which should be given by means of a shutter of the "blind" type, or with one of the Kershaw pattern. Supposing the lens to have been stopped down to about  $f/22$ , a rapid isochromatic plate used without a screen would require about a quarter of a second exposure. This is

assuming the sun to be obscured and very near the horizon, and the sunset to be a yellow one. Very beautiful effects are to be obtained in this way. For such work a screen is generally unnecessary, the yellowness of the sunset compensating for its absence.

For general landscape work it is not necessary to use a screen, though very often better results will be obtainable if one be used. In such case it should be very light in colour—a pale lemon yellow. The effect of the screen is to render the plate still less sensitive to violet and blue, therefore it will be seen that if too deep a colour is chosen the photograph will be untrue, owing to too much of those colours having been cut off. For copying coloured pictures, diagrams, or paintings, or for photographing flowers, a deeper screen should be employed, which will, of course, necessitate a much more prolonged exposure. For copying purposes, or for landscape work where the full effect of the process is desired, the medium rapid isochromatic plates should always be used in preference to the instantaneous. The use of a light screen will double or treble the exposure, and with a dark screen four or five times the ordinary exposure may be required, but when copying length of exposure is a matter of minor importance. No definite rule, however, can be given, and these times are merely approximate.

(To be continued)

## The Lantern, and how to Use it.

By C. GOODWIN NORTON.

(Continued from p. 400.)

### CHAPTER XII.

#### THE READING LAMP.

CHIEF among the minor troubles of a lecturer or lanternist is the reading-lamp, which seldom comes up to its requirements—a good light which will fall only on the book or manuscript, a certainty that it will burn for one and a half or two hours with freedom from smoke or smell, and be always ready for use without the necessity of cleaning and trimming each time of using. As the lamp must frequently be moved from one hall to another while full of oil, the contents must be safe from the risk of spilling.

In the back of the lamp is generally inserted a small piece of coloured glass which can be uncovered by the lecturer as an indication to the operator that the picture is to be changed, or that it is out of focus, etc. It is also usual to have a small bell underneath the lamp to call the attention of the operator to the signal if required.

The reading-lamps constructed to burn colza oil must be carefully trimmed and adjusted to the proper height, or they will smoke and smell, and the same may be said of those burning paraffin. To prevent the escape of the oil when travelling, a tight-fitting cap should be placed over the burner, as the case may get turned upside down, which frequently happens notwithstanding the fact that it may be labeled "This side up," "Glass," as all cases should be which contain optical apparatus. Lamps which have a candle in the form of a night-light often get so hot that the whole of the wax in the shallow vessel becomes fluid and is liable to do serious damage should it be accidentally moved when placed on the top of a piano, table, or other improvised reading-desk. A lamp having a spring to keep the candle at one height would answer the purpose well if it could be kept cool enough to prevent the wax from melting and stopping the action of the spring. For a carriage lamp used out of doors these springs are all very well, but when used inside a lantern-lamp the conditions are changed.

It may seem to the uninitiated a very simple matter to keep a small light burning a short time, and to properly shield its rays from falling anywhere but on the book, but only those who have tried to read a lecture know the inconvenience of holding one's head within a few inches of a heated lamp for one and a half to two hours, and to be in constant dread that it will smoke or go out altogether.

The best source of light would be a small gas jet enclosed in a case with a hood having a reflector inside to throw the light down, and a bent chimney at least a foot long could be easily constructed to carry the heated fumes well away from the reader. This description of lamp would be of little use made in a portable form, on account of the difficulty of getting a supply of gas in many places, but it would be useful in institutions and schools, instead of the makeshifts now so commonly used.

Mr. Hughes' Benzo lamp contains a material which absorbs the benzoline, the residue being poured out in the way common with spirit lamps; there is consequently no danger of leakage should the lamp be moved or upset. Another good pattern is that which burns paraffin and requires no lamp glass, the lamp itself forming a combustion chamber.

Mr. Wood's Lecturer's Reading Desk is very light and portable, as it folds up into small space when not in use, and the light given from the lamp is quite sufficient for readers of average sight to read their notes in comfort.

Some lecturers carry a tripod on which to fix their lamp and manuscript or book, but except for those who lecture every night this is unnecessary, as there is generally a table or desk, or stand to be had in most public buildings.

Mr. Chadwick supplies a portable reading-lamp and desk on a stand which are all concealed from the audience by a curtain, with a view to keep them in the dark as to whether the lecture is read or delivered. It also has the advantage of permitting only the head and shoulders of the speaker to be seen, which to a nervous beginner is a great relief.

*Mechanical Slides.*—Now that photographic apparatus and dry plates are so cheap, good, and easy to manipulate, the amateur will most likely make the greater part of his slides himself, at the same time most audiences expect something besides a series of plain photographs. The usual kinds of mechanical slides are comic slips; the lanternist will do well to avoid these altogether, unless showing to mere children; lever slides, which have part of the picture painted on a glass fixed in the frame, the other portion being on a cover glass which is held by a brass ring, and can be moved on its centre by a lever at the side; these are effective for such subjects as a ship rocking at sea, a horse drinking, or a man hammering. With all slides of this kind the glasses must be kept perfectly clean, or the dust will show how the movement is effected. There are also slides with eccentric movements to make a ship move up and down by turning a handle constantly in one direction. Sometimes three glasses are used in one frame, but this is seldom satisfactory, as two of them must be out of focus. Next we have rack-work slides, in which the glasses are mounted on the same principle as the lever, but the movement is by a rack and pinion, which revolves one glass, as in the case of smoke coming from a burning house or ship or volcano, or of the sails of a windmill, or two glasses in the case of a chromotrope, which is too well known to need description. Chromotropes are more effectively worked by a band on two wheels than by rack-work, but more liable to get out of order.

Perhaps the most effective of all mechanical slides is the one representing a ship sinking in mid-ocean. This always excites wonder as to how it is done, and yet it is very simple.

The sea, boats, and a little of the sky are painted on one slide. The second slide consists of two glasses, on one of which is painted the ship, which can be moved up or down as required, and on the other glass are the sky and a little of the sea. Each slide forms a little more than half a circle. They must be both brought on together, or half the screen will be blank; this necessitates the use of three lanterns. When the glass having the ship painted on it is lowered, or rather raised, the ship disappears behind the smaller or blank half of the slide. The two slides must, of course, be properly tinted near where they join, or the illusion will be spoiled. The motion of the ship sinking may be controlled by simple lever or by rack and pinion. The latter is the better, as a mistake is less likely to be made.

Another slide which shows to advantage is the train crossing a prairie or bridge. In this case it is not usually noticed that the wheels do not revolve.

Such slides as a man eating rats are now out of date, and are accountable in a great measure for much of the unpopularity of the lantern with persons possessing the slightest artistic taste.

The non-mechanical effects, or those having one or two simple movements, in many cases show to better advantage than the more elaborate ones, *e.g.*, the Houses of Parliament with the River Thames is shown first by day and dissolved into night, and if three lanterns are available, another slide can be introduced showing the windows lit up and the electric light from the clock tower. A double slip is then placed in the effect lantern. One slip gradually discloses the moon as if clouds were passing over it, at the same time lights up a portion of the river, which appears to ripple when the other slip is slowly moved. If this is carefully done and the slides properly in register, the effect is very natural.

The moon slide is easily made by blacking a plain glass, and tracing a little round hole with a small pair of compasses; the river is lighted by horizontal lines scratched on the black, which will show white on the screen. The ripple is produced by similar lines on the second slip. The first has irregular patches of black, representing clouds which are drawn across the moon, showing at last clear glass.

The best way to blacken glass if it can be quite covered and protected, is to thinly coat it with hot melted wax, and then smoke it in the fumes of burning camphor; or a gelatine plate which has not been developed will answer the purpose; either of these will give much finer lines than of the preparations of black usually sold.

A rain slide is made in this way, but the scratches must be made with discretion, or the rain will appear like bunches of candles on the screen.

Panoramic slides as a rule do not show to advantage, except in the case of ships or boats, because the figures glide, which generally spoils the illusion.

A snow storm requires two lantern. In one is shown the winter scene. The snow slide consists of a piece of opaque calico wound round two rollers, and through it are pricked a number of holes to represent snow; when the calico is passed upwards by winding it on to the top roller, the snow appears to fall across the winter scene. The operator must always take care to close the shutter of lantern or turn off the gas just before the end of the calico is reached, or the snow will appear stationary. It is usual to darken the scene a little before snow commences, and make it light again when the snowstorm is over.

The phantoscope or chorentoscope is a mechanical arrangement by which figures execute changes imperceptibly; it is very effective, but rather a delicate affair, and will not stand much rough usage.

(To be continued.)

## Holiday Resorts and Photographic Haunts.

### SALISBURY.

SALISBURY is a centre within easy distance of which the photographer will find much interesting work. The city is reached by the London and South Western Railway, after a journey of eighty-three miles from Waterloo. The Cathedral is of course

the chief object of interest. This is the most perfect specimen of early English work to be found in the country. An excellent distant view may be obtained with a long focussed lens from the river bank at no great distance from the station. A view from this spot formed the frontispiece of Vol. I. of the *Photographic Quarterly*. As one proceeds from the station towards the town a bridge over one branch of the Avon is soon reached; this must not be crossed, but a foot-path along the bank of the stream to the right-hand must be followed, the river being kept on the left-hand until a wooden bridge over a branch stream is reached; this must be crossed, for the best position for the view is just at the further end of this bridge. The best time for this view is early in the afternoon. The Close may be reached either by a short cut past the Church-house, or by retracing one's steps to the main street from the station. The great height of the spire renders it difficult to get a general view of the cathedral. The two best, both of which, however, require a wide-angled lens, which may be used here with less unpleasant results than usual, are one from the extreme N.E. corner of the Close, which should be taken before 9 a.m. or after 6 p.m., and another from the N.W., which should be taken between 1 p.m. and 3 p.m. There is no difficulty about the West Front; the North Porch also is worth a plate, and can be best done after 6 p.m. Permission to photograph the interior should be previously obtained of the Dean. The absence of coloured glass allows comparatively short exposures. A dozen plates may be exposed within the building; general views of nave and choir, of the Lady Chapel from one of the choir aisles, will probably be taken. A good view of the transepts may be obtained from the North, showing the "strainer" arch introduced to strengthen the steeple, while the tombs of Bishop Poore, the founder of the cathedral in the North

Choir aisle, and of Bishop Giles de Bridport, during whose episcopate the building was finished on the South Choir aisle, and of William Longspee in the Nave, and the cloisters and the Chapter House should not be neglected. If permission can be obtained from the Bishop to photograph in the Palace grounds, several charming views may be obtained of the cathedral from the south and south-east; perhaps the prettiest of these is one from the far side of the lake, showing the palace and cathedral.

There are two gateways leading into the Close, one from the north, the other from the north-east; each of these as seen from the outside is worth a plate.

The market cross, and the interior of St. Thomas' church (usually open and entered by a passage leading from the main street under an archway) should be taken. The painting of the "Last Judgment" over the chancel arch is particularly interesting.

These are the chief objects of interest in Salisbury itself, but there are several others in the neighbourhood. Britford Church, a little more than a mile along the river, with two Saxon doorways (which, however, can only be taken from the interior) should not be missed; the church itself forms a pleasing picture from the south-west.

Then there is Stonehenge worth some half-dozen plates, which may be reached either by driving direct from Salisbury, or by train as far as Porton, and then by a walk of six miles through Amesbury.

Some pretty views may be obtained on the river near Wilton, about three miles west of Salisbury, by train or by the road, which will lead the photographer close to Bemerton, with its quaint ivy-covered church, interesting from its connection with George Herbert. Wilton Park is very beautiful, but is not open to the public save on special occasions. The next station but one towards the west is Tisbury; two miles from this lies Fonthill, where the author of "Vatherk" built his Abbey and Tower; little of this building remains, and as it is situated in private grounds it is not at all times accessible, but several good views may be taken on the banks of Fonthill lake, which can be photographed without let or hindrance, as a public road runs through the park skirting the water.

About three miles from Tisbury in another direction is War-dour Park, through which a public road runs. Several good views may be taken here, especially of the old castle, twice be-

sieged and reduced to a ruin in the civil wars. A small gratuity, say a shilling, is expected by the gardener, who gives admission to the enclosure surrounding the ruins, but this formality and the inscription of his name in a book having been gone through, the photographer may stay as long as he likes, and expose plates

to his heart's content, on the ruins and the magnificent cedars around them.

Two other excursions may be made by rail from Salisbury; one to Sherborne about twenty miles past Tisbury along the main line, for the sake of the Abbey Church, and the other to Romsey on the line to Southampton, about fifteen miles from Salisbury. Here is a beautiful Abbey, built in late Norman, Transition and early English times. It is difficult to get any good general views of the outside, but the interior well repays the photographer for any trouble he may take. One object should by no means be over-looked—a representation of the Crucifixion almost life-sized carved on the exterior west wall of the south transept. Such a carving is nowhere else to be found in England, although a small one is carved on a buttress on the west front of Sherborne Abbey.

Plates, chemicals, and other photographic goods may be obtained of Mr. E. Baker, Fisherton Street, Salisbury.

T. PERKINS, M.A.

## A Holiday in Norway.

PHOTOGRAPHY AMONG THE FJORDS.

(Continued from page 493.)

### II. AALESUND, MOLDE, AND NAES.

At Aalesund came the first revelation of the number of photographers we had on board. The anchor was scarcely let go ere the sides of the boat were lined with amateur enthusiasts, all anxious to get their first photograph of Norway. There seemed to be no end to them. The familiar tripod was everywhere, and many a head was enveloped in the black cloth, the satisfied face that afterwards emerged showing that the judgment pronounced was a favourable one. Indeed, with such a scene in such a light, it could not be otherwise. This was one of the first things to be noticed in Norway—the marvellous clearness of the atmosphere. The "most pellucid air" of Greece can hardly surpass that of the land of the fjords. To eyes accustomed to the duller atmosphere of our own country the result was often very perplexing. Objects that seemed to be within a stone's throw were found to be really a quarter of a mile away. A mile or two expanded into four or five in this country, where the smoke and fog of our cities are things unknown. Such transparent clearness brought joy to the hearts of the photographers, and plate after plate was exposed, while the nimble "Kodaker" marched here and there with a happy countenance, secure of good and effective results wherewith afterwards to recall his first impressions of Norwegian scenery. A halt of some little duration was made at this picturesque port, for the chief steward had some unromantic but very far from unnecessary business to transact on shore. Meanwhile we leaned against the taffrail and feasted our eyes with the magnificent effects produced by the clinging clouds that now descended, girdling the lofty hills, and now lifted, exposing the whole height and length of a mighty inland range. The little jetty, crowded with men, women, and children, secured its share of attention, for the *City of Richmond* created no small sensation in the quiet town. It was by far the biggest vessel that had ever appeared in these latitudes, and many admiring and wondering eyes surveyed its graceful lines from stem to stern, and from stern to stem again. Boats, too, put off, some with fish to sell, and some with the results of the steward's negotiations, while others were filled with the young hopefuls of Aalesund, anxious for a nearer view of the big ship that had come to visit them. The fish seemed marvellously cheap, and were kept "all alive, oh!" by being towed astern in an ingenious little wooden device, shaped like a canoe, constructed so loosely as to admit the water, but closely enough to retain the fish.

#### THE FIRST FJORD.

The pilot and provisions on board, the order to heave the anchor was given, and we steamed slowly through the clustering islands, past Lepsoë—where Mrs. Mouat on the smack *Columbine* was stranded in February, 1886, after tossing helplessly in the sea for more than a week—and into the imposing Molde Fjord. This was our first fjord, and, great as were the expectations of those of us who were new to Norway, they were more than fulfilled. One takes up the map and sees the coastline all indented and broken up on the west, as if the more solid fabric of the country as it neared the sea were worn into a ragged fringe.

But the map can give no idea of the majestic beauty and the enthralling loveliness of those same fissures and indentations, which pierce many miles into the side of the land, and it almost seems as if they are utterly beyond the power of description. The words one vainly seeks to write of them are all too feeble, and do but move "upon the topmost froth of thought." On this day the Molde Fjord lay still and almost sombre as we entered it, for the weather was dull. But every now and then wonderful gleams of silver broke through the clouds that built up an "under-roof of doleful gray," and fell on the shimmering water, while the shifting mists that encircled the guardian hills loosed their white scarves at intervals, and revealed the flashing sun-kissed snows on the higher peaks and the tiny rills that fell all milky-white with foam adown the steep hill-sides midst scattered stones and dark-green firs. Molde, ere long, lay full in view, picturesquely built on the narrow green slopes between the wooded hills and the fjord, a striking contrast in its neat and trim appearance to Aalesund. Molde has more the air of a fashionable watering-place, and is largely patronised by the Norwegians themselves as a holiday resort. Fine views are to be obtained in all directions, the Romsdal Mountains being easily distinguishable. To see them, and not Molde, was then our immediate aim; so, having taken a peep at the place, and been boarded by a customs officer, the ship was headed for the Romsdals Fjord, and early in the evening arrived at Veblungsnæs.

#### NO DARKNESS AT ALL.

Here for the first time the inconvenience of the delay in starting from Liverpool was felt. The excursion through the Romsdals Valley, which had been planned, could not be accomplished under six or eight hours. But the long Norwegian day came to help us. Ever since leaving England the day had been lengthening and the night dwindling, and when Norway was actually reached, we found no darkness at all. The sun was never below the horizon for more than an hour or two, and ere the sunset flush had left the sky, the rosy glow of sunrise mingled with it. Under such circumstances one hesitated to go to bed. It seemed a sin to sleep while all the world was light, and on this evening it was resolved unanimously that we would not go home till morning. So the boats were ordered out, and the steam-tenders with which the ship was provided were soon busy in conveying passengers ashore. Of Veblungsnæs there is nothing to say, except that it is the nearest posting station for the Romsdals Valley, and that it contains the Hotel Bellevue, kept by M. Aandahl. The hotel is a real traveller's joy. Surrounded on all sides by mountains, every window commands a magnificent view, here of the fjord and there of the famous valley.

The visitor who enters it should muster up all the Norse of which he can boast, for that will bring a smile to the face of the buxom damsel who waits on him, or speak in English if he knows not Norse, for she will understand him perfectly, and call for dinner. Then delicious trout and unspeakable pancakes and other Norwegian delicacies not to be described, and the pleasant sparkling *Bayersk öl* that seems to be the usual beverage offered to visitors, will teach him that Norse fare is by no means to be despised. Thus fortified the Romsdals Valley may be attacked, even after 8 p.m., and in a misty rain. Undoubtedly the best way to see this glorious valley is to walk through it; but the way was long and time was short, and so we had to requisition the *carrioles* and *stolkjærres* that were picturesquely grouped in front of the landing-place. These are the universal means of conveyance in Norway, and admirably adapted they are to the nature of the country and to the strength of the swift and sure-footed ponies that draw them. A *carriole* is just a light two-wheeled vehicle made to carry one person and his luggage, and able also to accommodate the postboy behind; while a *stolkjærre*, also two-wheeled, is adapted for carrying two people and the postboy. Both are most comfortable conveyances, especially if one makes one's *skydsgut*, or postboy, merely an ornament, and drives oneself. The ponies scarcely need driving, however, so nimbly do they trot along the hilly roads; only it must be remembered that in Norway the rule of the road is to keep to the right when meeting a vehicle, and to the left when overtaking one.

#### ROMSDALSHORN AND TROLDTINDERNE.

Starting then from Veblungsnæs, the road first ascends sharply and crosses the Rauma, than which no prettier stream is anywhere to be found, even in Norway. Here it foams and roars over a succession of boulders, churning its dark blue waters into

## ADAMS & CO.'S PHOTOGRAPHIC ANNUAL FOR 1892-93.

384 Pages. 500 Illustrations. Price 6d., post free 1s.

Contains Articles by all the leading writers, and particulars of a number of novelties that appear in no other Price List whatever. Everything is alphabetically arranged and tabulated, and it is undoubtedly the most clear and comprehensive work embracing Photographic Apparatus and Appliances ever published. Those possessing a copy require no other List whatever, as it contains MORE than all other Price Lists put together. This is achieved by condensing and tabulating sizes and prices, thus giving any information required at a glance.

**IT IS RIGHT UP TO DATE.**

The "OPTICIAN AND PHOTOGRAPHIC TRADES' REVIEW" says:

"We have received from Messrs. Adams & Co., of Aldersgate Street, and Charing Cross Road, a copy of their 'Photographic Annual' for 1892-93. It is as complete a catalogue of photographic goods as can be desired by the most voracious of buyers, and extends to 384 pages. The catalogue is rendered additionally attractive by some introductory chapters of well-written articles by workers of repute, such as Captain Abney, H. P. Robinson, W. Jerome Harrison, Andrew Pringle, Walter D. Welford, Chapman Jones, John Howson, etc.—The catalogue is well compiled and well printed, and evidently costs the publishers many times the nominal sixpence at which it is sold."

## UNSOLICITED TESTIMONIAL.

"Haileybury College, Hertford,

"Messrs. MARION & Co.,

May 24th, 1892.

"I wish to take this opportunity of saying how much I have benefited by the Actinograph. I have had a great deal of copying prints, etc., to do in a room here, and after one or two experiments to decide on the special factor necessary under the conditions, I settled down to be guided entirely by the Actinograph as to exposure. Out of the 300 or 400 negatives I have thus taken, I have had so few failures that I attribute them entirely to my carelessness. Yet I have followed the Actinograph in all conditions of weather, and at all times of the day, from January to May, with plates of different speeds, and with varying stops. I have had but little experience out of doors with it. What I have had has been as satisfactory as indoors.

"I am, yours faithfully, Rev. W. D. FENNING, M.A."

**MARION & CO.,**  
**22 & 23, SOHO SQUARE, LONDON, W.**

snow white foam; there it sweeps placidly and smoothly along under the dark shadow of the hills; at some sharp bend it is overhung with trees, and where the valley opens it ripples merrily on amidst fields and flowers. The Rauma and the conical peak of the Romsdalshorn—that has only three times been scaled, once by an English lady—and the fantastic crags that the Troldtinderne uplift to the sky keep one company all the way along the valley. In the gardens of the houses that we passed the apple trees were in full bloom, and all along the road a tree, said to be hickory, lit up the twilight with the glimmer of its white flowers and filled the air with fragrance. Graceful birches leant over the road springing up from beds of fern, and higher up the firs gave colour to the dark-hued rocks. On either hand in the vivid green of the meadows lay the marsh marigold in clusters of virgin gold, and ever and anon the violas threw a mantle of true blue over the green, so thickly did they grow. Such richness of vegetation below, such majesty of mountains above, gave to the valley a solemn grandeur and a weird beauty that sufficiently accounted for the legend as to the origin of the Troldtinderne. These are the Pinnacles of the Trolls, and their broken and irregular summits, 6,000 feet high, as seen against the sunset sky, suggested the story of the belated wedding party who, while on their way home over the lofty mountains, were turned into stone by supernatural agency. The lateness of the hour perhaps worked on the feelings; perhaps the thunder of an avalanche that fell ahead of us as we drove along the valley suggested strange fancies, but, however it was, one could almost imagine that the phantom figures of trolls and goblins kept pace with the *carroles* in that midnight excursion through the twilight valley. For though the soft clouds above the hills were daintily flushed with rose, and the hill-tops themselves stood out clearly in the light of day, a semi-twilight reigned in the valley and added a vague and mystic beauty to the scene.

Just beyond Horgheim ten miles or so from Veblungsmæs, is the Mangefos Fall, the finest of all the waterfalls along the valley, and however limited one's time this should certainly be visited. These falls, finding their origin in the snows above, often thread their way for two or three thousand feet down the mountain side, lacing the rocks with silver, and filling the air with their musical murmur. The Mangefos, as its name implies, is a group of streams that now unite and now divide, and finally unite again, and hurl down the cliff in foaming and headlong confusion. Beyond this fall and on to Fladmark there are still fresh beauties to be seen in the ever-changing views of rocks and streams, and hills and falls; but further than this we could not go, and so the ponies gladly turned homewards and arrived at Naes still fresh after a drive of thirty-two miles. The air of the fjord was cool after that of the valley, and leaping trout made rings on the surface of the still water, as we rowed on board at some unearthly hour in the morning!

(To be continued.)

## Clouds.\*

BY ROLAND WHITING.

AMONG the many subjects which come within the study of the photographic enthusiast, there are none which require so much care and thought as the printing-in of skies. To the artist the sky often means the picture itself, for in most of the production of great artists we find the sky occupying the greater portion of the picture; and it is generally in the sky that the artist produces his grandest effects. In the same way the photographer should give his attention and thought to the introduction of skies to his pictures, and, with this end in view, he should make close study and observation of the various forms of clouds and the conditions under which they appear. This advice may seem to some to be unnecessary, for they will say that if it is required to introduce a sky, and the clouds contained therein conform to the general lines and balance of the picture, they have all that is wanted. To this I would answer by reminding them that above all things truth must be embodied in their pictures if they would ever have them looked upon as works of art, and such can never be the case if their skies, though correct as regards balance of lines and chiaroscuro, be at fault as regards their nature. It may be asked then if this difference in the various kinds of clouds is sufficient to call for special investigation, and I would say

undoubtedly, for clouds which are formed at one season and under one set of conditions do not always occur under others; and it would scarcely be any more absurd to represent a nurse-girl with her perambulator climbing the Himalayas than introduce a wrong description of clouds into a landscape. It is therefore the intention of the writer to endeavour to describe the various forms of clouds, and notify the seasons and times in which they occur. The reader will thus be introduced to the study of meteorology, but in this article as much avoidance of the use of scientific terms will be made as possible, so that the description will be rendered more clear. Meteorologists divide all clouds into seven modifications, three of which are considered primary, and four which appear to be combinations of these primaries. It will therefore be best to describe and comment upon them in their usual order, commencing with the three primary forms.

The first of these is known as the *cirrus*, commonly called the mare's-tail cloud. This is the highest of all clouds, and consists of wavy, parallel, or diverging fibres. It is the first form of cloud to appear after sunrise, and the last to be seen at sunset. It is often seen as a light cloud against a darker sky long after the sun has disappeared, and can therefore be used with great effect in that way in pictures representing the gloaming. In fair weather small groups, and threads of cirri running in an oblique direction from leeward to windward are usually seen; but in wet weather it forms itself into horizontal sheets, and before wind and rain we often find its edges attended by fibres brushed upwards and backwards, especially from the south-west. When these fibres point downwards it is indicative of immediate fine weather. When steady high winds are prevalent, streaks of cirri are seen streaking across the sky, therefore a sky containing clouds of this form would be the most suitable to print into a picture of ships being driven at a good rate across the sea or along a river. It is this form of cloud and its modifications which give existence to halos and phenomena of like nature.

The next form of cloud to be observed is one of the commonest kind which cross the sky. It is known as the *cumulus*, or "day cloud," and sometimes as the "summer cloud," on account of its greatest frequency at these times. It is only formed in the daytime, and is very distinct in shape, having a horizontal base which is sometimes remarkably flat. It is built upwards into large conical heaps resembling mountains, which it frequently rivals in size, and owing to this shape is exceedingly useful in pictorial composition. In fair weather it begins to form some few hours after sunrise, attaining its greatest bulk about midday, and gradually diminishing in size towards evening, totally disappearing as night sets in. Fine, fair summer weather is attended by cumuli of moderate size, and pleasingly rounded shapes floating at a moderate height, and in calm weather they are also found in like manner; but previous to rain these clouds increase considerably in size and blackness, and gradually lower, their surfaces becoming covered with loose fleeces. When cumulus clouds increase in size and number as night sets in, instead of dispersing, they indicate a storm during the night, and when they assume a very spherical form and are very white, they are the heralds of thunder, and as this approaches they become very heavy, dark, and hard in outline, rolling over each other in angry-looking masses.

The next cloud to receive our attention is very widely different from the two preceding forms. It is scientifically known as *stratus*, and commonly as the "night cloud," for reason of its only being formed at night. It is a horizontal strata of cloud resting on the surface of the earth, forming as night sets in and dispersing as the morning sun's rays warm the air, when it rises, and finally forms itself into the cumulus modification. It is this cloud which produces mists and fogs, and as it is seldom formed except at night, it is of little service to photographers, save for early morning or late evening effects. The writer has often been charmed by the pleasing appearance produced when the rising sun casts slanting shadows through the trees upon the morning mists. Such an effect as this is found previous to a fine October day, when these mists seem slow in dispersing. Another instance is when this cloud settles down in the valleys and low meadows, allowing only the tops of trees and other rural objects to be seen above it. When this cloud assumes the state described in these two instances, the finest and most serene weather is always prevalent.

Such then is the appearance and description of the weather attending the three primary forms of clouds. From these all other

26. Stolze's "Instructions."

If we consider the above table more closely, we shall find that most of the toning baths included in it consist of water, hypo, sulphocyanide of ammonium, alum and chloride of gold, whilst those which are specially intended for collodion papers contain besides these ingredients generally some lead salt.

Baths Nos. 18 and 19 in the table are conspicuous in that they contain no gold, but only hypo and nitrate of lead, the latter bath as a necessary ingredient also alum, and No. 25 which only contains hypo and gold.

On the action of the individual ingredients of the toning and fixing baths as we use them to-day, up to the present time no examination has been given.

Chloride of silver prints present as a rule an unpleasant tone, if they have been fixed in a neutral fresh fixing bath; the tone, which approaches a brick-red, turns, if the print is placed in an old or with acetic or citric acid acidulated bath, gradually to a brown.

Blanquart Evrard\* described this action of old partly decomposed hypo solution, and stated as the cause of this behaviour the action of the silver nitrate on the hyposulphite of soda; he also recommended then the addition of acetic acid to the fixing bath. The actual basis of this toning is in any case the formation of sulphide of silver, since the hyposulphite of soda, as well by long standing as also by the addition of small quantities of dilute acids, suffers a decomposition into sulphurous acid, or sulphite of soda and sulphur, which decomposition may be represented by the following equation:—

Hyposulphurous acid      Water      Sulphur      Sulphurous acid.

This decomposition, however, does not take place quickly, but the liquid contains, even after standing for weeks, always still small quantities of hyposulphurous acid. If a plate of silver is now placed in an acidified solution of hyposulphite of soda, it is blackened by the formation of sulphide of silver. Many salts, especially the acid salts and alum, act similarly to the weak acids. If a solution of hyposulphite of soda is mixed with a solution of alum, a cloudiness soon appears, consisting of precipitated sulphur and aluminium oxide. This decomposition may be expressed by the following equation:—

This decomposition takes place very slowly. If a print on chloride of silver emulsion paper, celloidin or aristotype is now placed in the filtered solution, it becomes first yellowish red, then brown, and after longer action grey-brown, and unpleasant. If several prints are toned, however, in the same solution, they are later evenly toned brown, the reason of which is that the hypo has taken up silver salts, chloride, acetate, and citrate of silver, from the film of emulsion, which form the hyposulphate of silver, or the double salt:—

and this salt considerably influences the sulphurisation or sulphur toning of the silver image.

I carried out the experiment of toning with alum and hypo with the following solution:—

Solution of hypo, 20 per cent.	...	...	...	125 parts.
alum	...	...	...	20

The liquid became turbid very quickly, was filtered, and in the clear solution some prints were fixed and toned, one after the other. The first prints showed after ten minutes' action the greyish-brown tone, whilst the third and following prints attained the ordinary photographic tone. This observation ought to be the reason why it has been so frequently recommended to add either nitrate of silver and chloride of ammonium or sodium to the combined toning and fixing bath, or before use to fix in the same clippings of sensitised paper.

The same result as with alum is obtained by the use of acid fixing baths, for which purpose citric acid is specially suitable; in this case also, the hyposulphite of soda is decomposed into sulphurous acid and sulphur, which latter *in statu nascendi* causes the formation of sulphide of silver.

(To be continued.)

## Societies' Meetings.

**Brixton and Clapham.**—On the 21st inst., Mr. W. H. Smith, of the Platinotype Co., demonstrated the working of their new cold-bath paper, pointing out its advantages over the hot-bath method. Among these was the power placed in careful hands of local development by treatment of the print with glycerine. Where solarization of the dark parts of the print was to be feared, or where parts might with advantage be rendered in a lighter tone than the undodged print gave, glycerine was applied just before development, by which means the process was retarded, and the granularity which sometimes characterised prints by the hot-bath method, in such cases, was conspicuous by its absence. The glycerine might be applied with a brush or sponge or might be boldly rubbed on with the hand. The whole print might be treated thus, and the development effected by means of the brush and with oxalate solutions of various strengths. Contrary to expectation no harsh outlines were visible in the finished prints thus treated. On the 25th inst. the annual excursion to Bexley took place, by invitation of Mr. Dresser, the late President. Fair, though cloudy weather attended the efforts of those present, whose attention was fully occupied by the subjects found by stream and on farm. After tea, Mr. J. W. Coade, V.P., on behalf of the members, asked Mr. Dresser's acceptance of an illuminated address expressing their thanks for his services during the three years he has held office.

**Hackney.**—At the meeting held on the 23rd inst., Dr. Gerard Smith in the chair, Mr. Hensler showed a yellow negative, and asked how to remove the stains. It was said that prevention was better than cure, and sulphite soda was recommended in the developer. Mr. Capel asked how reduction took place on a light fogged plate. It was answered by saying that the silver was unequally dissolved. It was recommended that a fogged plate reduced and intensified would give greater contrast. The chairman recommended a weak reducer. The excursion for Saturday was altered to Carshalton. Mr. Hudson showed cheap dark slides made by Chipper. Mr. Grant said he had exposed a Sandell plate in the Forest. It was dark under trees, with patches of bright sky showing, used *f*/20, and gave 20 sec. about 6 o'clock, without getting any halation. The assistant-secretary distributed samples of Eastman's gelatino-chloride paper. The report given by Mr. Hensler of the Barnet plates (distributed at last meeting), was that they were very good. Mr. Barker then opened a discussion on Orthochromatic plates. The chairman said if we looked through a purple glass at a view we should see the immense amount of reds in nature. These, he said, orthochromatic plates brought out. An ordinary view taken in average light may be no better, but in a yellow light there was a marked advantage. Mr. Dando said, "The Million" used a dyed screen to obliterate all colours but one, which gave a relief to print from. Mr. Grant had used ortho plates for two years, and said in foliage there was a marked advantage over ordinary plates. It was announced that the next meeting would be on Tuesday, July 5th, at 206, Mare Street, the club's new quarters. Visitors are welcome to any meeting. Particulars of membership can be obtained of the Hon. Sec., 12, King Edward Road, N.E.

**Holborn.**—On 24th inst., Mr. Fred Brocas in the chair. A number of slides by Mr. John A. Hodges were thrown upon the screen, including some excellent figure studies and views of North Wales, Devonshire, Haddon Hall, and Hampton Court. These were followed by some members' slides of Messrs. Cobb and Baker. A number of slides illustrating the "Detection of Crime" concluded the lantern show.

**Hove.**—On the 14th inst. Mr. E. J. Bedford read a paper on "Artistic Photography," illustrated by twenty examples by Mr. Sutcliffe (kindly lent for the occasion) and by a number of his own photographs. Mr. Bedford gave very valuable hints upon composition, selection of subject, etc., and practical suggestions for photographic work. What to aim at and what to avoid in picture-making was carefully pointed out, and the various points illustrated by the charming selection of photographs shown. Some discussion followed, and a vote of thanks proposed by H. H. Taylor, Esq., who presided, was heartily accorded Mr. Bedford for his paper, and also to Mr. Sutcliffe for the loan of his pictures. Four new members were proposed. Work done at the excursion to Poynings was passed round for criticism. The Secretary announced that the Town Library Committee had acceded to their request that two photographic journals should be supplied to the public reading room, the Club contributing the *Photographic Review of Reviews*.

**Liverpool (Camera Club).**—The usual meeting was held on 22nd inst., Mr. Jas. Hawkins in the chair. The minutes of the previous meeting having been read and confirmed, reports of the club excursions were read by the various leaders, viz., Rossett by Mr. W. A. Brown, Chester by Mr. W. Tansley, and Ince Blundell by Mr. J. H. Jones. The reports, besides recording much useful information *re* "light," "exposures," etc., were bright and vivacious, and provoked much mirth among the members. The subject for the evening was a de-

\* *Dingler. Polytech. Journ.* 104, p. 52.

monstration by Mr. W. Anderson Brown on the "Kallitype Process," and which Mr. Brown made most interesting and practical. Messrs. Archer and Sons exhibited their new two-guinea Repeatograph hand-camera, and also showed specimens of Brown's mechanical process of printing from negatives and toning without gold on gelatino-chloride paper.

**North London.**—On 21st inst., Mr. W. T. Coventon in the chair. After the usual preliminaries, Mr. A. J. Spiller showed some fine prints by the new cold bath platinotype process, taken from whole-plate negatives; Mr. B. J. Grover a series of hand-camera pictures taken in Cambridge, on Edwards' Isochromatic films; and the President, Mr. J. Taylor, showed a new stereoscopic shutter made for him for use at the convention. The Secretary called special attention to the next meeting of the Society to be held on July 5th, when Mr. Howson of the Britannia Works Co., Ilford, would introduce the subject of "Isochromatic Photography." A copy of the Ilford "Manual of Photography" had been received for the Society's use, and samples of the Eastman Co.'s new chloride printing-out paper received for trial were distributed to the members. Mr. J. Traill Taylor then gave a conversational lecture on "Photographic Lenses, Ancient and Modern," in which he compared the lenses in use by photographers prior to 1865 and about that period with the lenses now in use, describing fully their principles and construction, and illustrating his remarks by diagrams, and by the exhibition of a large number of lenses of all kinds, which were passed round for inspection. The lecture was highly appreciated.

**South London.**—On 20th inst., the President, Mr. F. W. Edwards, in the chair. Mr. F. W. Griggs was declared the winner of the award for the best print from a negative on Imperial plates. Mr. James A. Sinclair then read a paper on "Hand-Camera Work." The lecturer said the use of hand-cameras was now becoming recognised, special classes being set aside for work not in recent exhibitions. He was in favour of a camera with a lens of about  $4\frac{1}{2}$  in. focus, working at  $f/8$ , but he usually worked with  $f/10$  or  $f/16$ . The shutter should work in the diaphragm slot, opening and closing right across the lens centre, so that as much light as possible could be admitted during the time of exposures. The changing of plates should take place in the simplest manner possible, *i.e.*, automatically. For development he advocated the use of pyro, getting as much detail as possible, and then strengthening the negative if necessary. Mr. Sinclair's remarks were criticised by several of the members present, in which some divergence of opinion was expressed. There was an attendance of forty. Messrs. R. and J. Beck exhibited and explained their "Frena" hand-camera, together with some enlargements from negatives made with it. Messrs. Houghton did the same with their "Shuttle" hand-camera, showing specimens of work produced by it.

**Spen Valley.**—A meeting was held on the 14th inst., Dr. Sutherland presiding. The annual exhibition of the society was held and prizes were awarded as follows:—Enlargements: 1st prize, Mr. R. Smith; 2nd, Mr. J. H. Jackson. Portraits and figure subjects: Mr. J. H. Jackson. Architectural or Interior: Mr. J. H. Jackson; 2nd, Mr. Burnhill. Landscapes: Mr. J. H. Jackson; 2nd, Mr. R. Smith. Lantern slides (three to form exhibit): Mr. J. H. Jackson (withheld). Dr. Sutherland also offered a prize of materials value 10s. 6d. for the best photograph of a subject to be selected by the Council.

## SOCIETIES' FIXTURES.

- July 1.—CROYDON.  
 " 1.—LEWISHAM.—An Evening with Mr. E. J. Wall.

Mr. A. R. Wormald, of Sutton, Surrey, the manufacturer of the photo omnibus, has instituted a prize competition in connection with the same, which has resulted in the first prize of two guineas being awarded to Mr. Henry Staynes, of Clapton; the second prize of one guinea to Mr. A. E. Ironside, of Sutton; and the third prize of half a guinea to Miss E. Boord, of London. A second competition has now started and will close on October 31st, full particulars may be obtained from Mr. Wormald.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### QUERIES.

5736. **Dark Tone for Silver Prints.**—Could any reader help me with my toning bath? I have used both borax and acetate baths, but can't get the faces, ties, etc., of persons, and the clouds in views, to come out white, and the colour of the tone is all a dull slate colour. I should feel greatly obliged to any amateur who could help me out of this difficulty. I might also state I have used both pink and white silver paper.—CYMRO.

5737. **Keswick.**—I am going to Keswick for a fortnight's holiday in July, and would be glad if any reader could inform me whether there is an available dark-room in the town, and if I can obtain Ilford plates (yellow and white labels) there.—C. A. R.

5738. **Touring.**—I am much obliged to B. L. for the answer to my query, and should be very glad if, in addition, he would give me full particulars of successful exposures on one or two typical Swiss subjects, so that I may have some guide to go by?—H. C. LEAKE.

5739. **Hypo in Toning-Bath.**—What is the object and action of the small proportion of sodium hyposulphite (about 1 gr. per 8 oz.), recommended in many toning-baths for gelatine-chloride paper, and

why is it never included in baths for albumen silver paper?—H. C. LEAKE.

5740. **Watkins's plates.**—Can any one inform me what plate numbers suit these on Watkin's meter, *i.e.*, the "Ordinary," the "Instantaneous," and the "Special"? Mr. Watkins states them to be 5, 33, and 40 respectively, but this does not at all agree with the makers' estimate based on that of Mr. Warnerke, who gives them in the following proportion on his sensitometer, viz., 16 sec., 5 sec., and 1 1-3rd sec., or expressed otherwise, the "Instantaneous" require four times the ordinary, and the "Special" fully twelve times.—MORNINGSIDES.

5741. **Enlarging Negatives.**—Is it possible to obtain as good results by using a quarter-plate camera, making positive transparencies, and from them enlarged negatives of  $8\frac{1}{2}$  by 6 $\frac{1}{2}$ , as by taking negatives direct in a whole-plate camera? Will any one kindly give his experiences?—W. M.

5742. **Ross.**—Will any one kindly state which stop I should use, that a Ross No. 2 C. D. V. lens should cover a half-plate, or will it not cover it?—FRA.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

### ANSWERS.

5714. **Dark-Rooms.**—Ramsgate: E. Bailey, 9, Queen Street; Pavey and Co., 104, High Street. Margate: W. S. Harvey, The Central Pharmacy, 20, Market Place; and G. E. Houghton, The Stodart Studio. Dover: W. Wyles, 1, New Bridge; J. E. Whorwell, 7, Bench Street; M. Jacquette, Northbrook House. Brighton: S. B. Harcastle, 71, East Street; J. Wil-

liamson, 144, Church Road, Hove; A. D. Norman, 9, North Street Quadrant.—EDITOR.

5716. **Photographing in London.**—You can photograph almost any public building from the street; the parks only by permit. Use both hand and stand cameras.—O. L. M.

5719. **Gold Depositing.**—The deposition of gold may be caused by impurities carried into the bath by the prints, by the action of light, dirty bottles, or keeping too long.—EDITOR.

5720. **Hypo.**—This salt will keep well in any vessel with tight-fitting cover, and in solution in a well-closed vessel almost indefinitely.—EDITOR.

5721. **Film Carrier.**—Almost any metal sheath as used for plates, with a piece of cardboard behind film, should answer. Try Fallowfield, Adams, or Edwards for the same.—O. L. M.

5722. **Long Focus.**—The advantage of using long focus lenses is that all objects appear larger, for instance if the focus of single combination is double that of the doublet then the objects will be twice the size. At the same time sometimes the perspective is far more pleasing.—EDITOR.

5724. **Developing.**—A good deal depends upon personal opinion, and it is questionable whether any particular method will fetch out more detail, though it is possible by soaking the plate in ammonia first to obtain softer negatives.—EDITOR.

5726. **Negative Making.**—The only thing to do is to set the print up and copy it in the camera in the ordinary way. From the negative thus obtained prints or lantern slides could be obtained.—EDITOR.

5728. **Chloroplatinite of Potash.**—G. B. should purchase from the Platinotype Company, Southamp-

ton Row, W.C., a 60-gr. tube of the chemical, and then dissolve it in 60 drms. of water. The solution will keep any length of time. For use he should take 1 drm. of the stock solution, add 2 or 3 drops of nitric acid and 4 oz. of water. This bath can be retained and strengthened by addition from the stock solution as occasion required; further acid will also have to be added occasionally.—F. H. A.

5729. **Pinholes.**—The fault is not due to late development. It is probably due to the fact that G. B. C. did not carefully dust the plates before and after exposure. If he did so, the pinholes are caused during the coating of the plates.—F. H. A.

5729. **Pinholes.**—Probably you omitted to dust your plates before exposing, or else the pinholes were caused by air bubbles on the surface of the plates during development. It is not likely that the fact of keeping the plates for a few days before development would cause pinholes.—P. HARRISON.

5729. **Pinholes.**—It is most extraordinary that the Ilford plates developed by G. B. C., were full of pinholes, as the "Ilford's" are the best plates in the market; it is certainly not on account of having not developed them at once, but most likely they have been left in a damp place.—FRA.

5730. **Changing Bag.**—To my opinion, the best and most efficient changing bag can be got at Watson's, 313, High Holborn, their pocket changing bags are very portable, and the price of them are, for half-plates, 7s. 6d. The advantages they have are especially their portability and convenience with absolute impossibility of light entering into it.—FRA.

5730. **Changing Bag.**—Dollond, Fallowfield, Adams, and Beresford all sell changing bags, see the advertisement columns, prices from 7s. 6d. upwards.—EDITOR.

5731. **Exposure.**—In Germany light is about from 20 to 30 per cent. more actinic than in England.—FRA.

5733. **Zinco-Engraving.**—Abney's Instruction in Photography, price 3s. 6d.; Burton's Photo-Mechanical Printing, price 4s.; Wilkinson's Photo-Engraving, Colotype, etc., price 5s.—EDITOR.

5734. **Hydro cum Eiko.**—"Ignorance" cannot do better than prepare the four following solutions, as he will then have the development of all and every subject under his control:—

1.	Eikonogen .. .. .	120 gr.
	Pure neutral sulphite soda .. .. .	480 "
	Distilled water .. .. .	to 10 oz.
2.	Hydrokinone .. .. .	120 gr.
	Soda as in No. 1 .. .. .	480 "
	Water .. .. .	to 10 oz.
3.	Carbonate potash .. .. .	4 oz.
	" soda .. .. .	2 "
4.	Bromide potash .. .. .	10 per cent.

For use, take for detail No. 1, 1 drm.; for density, No. 2, 2 drms.; for speed, No. 3, 2 drms.; water, 1 oz. "Ignorance" will find that with the above he will have a developer combining cleanliness with all the advantages of pyro, and one which I have found to give more detail than pyro, without the slightest trace of fog.—CYMRODINIAN.

5734. **Hydro cum Eiko.**—The mixture makes an admirable developer, giving negatives from which beautifully soft prints can be produced. A good formula is that given in Answer 5703, snap-shot developer, of the last week's number.—F. H. A.

5734. **Hydro cum Eiko.**—I have lately been using eiko, in combination with hydro for developing plates (Ilford ordinary), and much prefer the combined developer to either alone. I get the soft effects of the former with the density produced by the latter. I use the formula recommended in the Ilford manual, viz.—

Eiko .. .. .	50 gr.
Hydro .. .. .	40 "
Sodium sulphite .. .. .	160 "
Water .. .. .	to 10 oz.

For alkali use the same as for hydro alone (Ilford formula), viz.—

Soda hydrate .. .. .	90 gr.
Water .. .. .	10 oz.

Of course, a solution of 10 per cent. bromide of potassium can be used, if necessary, in cases of over-exposure.—S. C. B., Genoa.

## EDITORIAL.

J. T. H.—The swing-back should have been used so that the plate was exactly upright. The plate must always be upright.

B. J. J.—There is nothing to take out the marks caused by the printing ink. Let it be a warning to you for the future.

J. H.—Please see "Our Views," p. 483, of last week's issue, which excludes your query. Write to us more fully as to what you want, and we will answer. There is no stripping required for any xyonite or celluloid films. They are treated just like glass plates, and are printed from like plates, though a sheet of glass has to be placed in frame to ensure absolute contact.

F. O. LANE.—Many thanks for information.

ANXIOUS.—It is a very difficult matter. A weak solution of cyanide of potassium is recommended. Try sulphocyanide of potassium 20 gr., water 1 oz., allow to soak for ten minutes, and then dip in a solution of

ferridcyanide of potassium of same strength, then wash well and dry.

RICHMOND.—Can you call upon us any morning next week, and we will ferret out all you want to know, or if you will make appointment we will try and keep it.

R. P.—Try Watkins' exposure meter. For shutter a simple drop, or Tylar's window-blind shutter. If you could send us up a negative we would see what was the matter. The Britannia plates are not the same as the Ilford. The calculation of exposure with a pinhole follows exactly the same law as lenses, i.e., divide the distance between plate and pinhole by aperture of pinhole.

INDIAN PLATES.—Your query cannot now be inserted, but we answer by post.

J. GABRIEL.—We cannot get brilliant prints on the paper, (due probably to improper keeping). You can recover the platinum by burning the paper, carefully collecting the ashes, and treating with successive portions of aqua regia, evaporate the solution till excess of acid is driven off, add some ferrous oxalate developer, allow the precipitate to settle, collect, wash, and dry, or else dissolve up for use. The new cold bath AA paper is the best, most decidedly.

H. CRISP.—Entry forms sent on. You can send one print on y each class.

CAMERA.—(1) The changing box is as good as dark slides, and much less weight. (2) Metabisulphite of potash is an acid salt, and therefore you ought to add more ammonia to the developer. It preserves the pyro longer than sulphite, but will, as you have found, act as a restrainer. (3) The average time required to finish a print from a negative of average density varies so much with the light that we cannot give you any definite answer, but about 4 to 6 hours, including printing, toning, fixing, and washing. (4) The exposure depends, of course, on the light, but about five minutes, we should say. Under-exposure and under-development are probably the cause of your dirty whites.

FARRO.—Nievsky's plates must be developed with the following:—

Carbonate of soda .. .. .	1 lb.
Sulphite of soda .. .. .	1 "
Dissolve in 1 quart of water, and add—	
Hydroquinone .. .. .	2 oz.
Bromide of potash (10 per cent. sol.) .. .. .	2 "
Saturated solution of hypo .. .. .	3 "
MELITA.—Blisters are merely local frilling. If they appear in or after the fixing bath use the combined alum and hypo bath made as follows:—	
Mix saturated solution of alum .. .. .	1,000 parts
With .. .. . sodium sulphite .. .. .	300 "
Then add—	
Solution of hypo (1:4) .. .. .	1,250 "

Be careful of the temperature of your solutions; keep them as cool as you can, and all of the same temperature.

L. R.—Letter by post.

HOSPITAL.—We would suggest an iso. as the best. You can develop, and then wash well and immerse the plate in a mixture of chrome alum, sugar, citric acid, and sulphite of soda, but if you must develop whilst away, then fix also; don't leave it till you come back.

E. W. MALE.—Try Fitch, 34, Angell Road, Brixton, for matt celluloid sheets. You can use the old platinum salt by mixing the baths suggested on p. 493 of last week's issue.

W. L. C.—We have not any data, but will try and get some for you. You will find it much cheaper to buy lenses.

ALPHA.—Send up camera, by all means.

C. DAWSON.—Many thanks. Paper shall appear next week.

MORNINGSIDE.—Please see our note re queries in last week's issue.

W. M.—You would find the "Aptu" Universal hand-camera, made by Sharp and Hitchmough, of Dale Street, Liverpool, answer your requirements.

X. Y. Z.—By all means use the red label plates. You may not want the extra rapidity, and can then stop down, but it is convenient to have it in reserve if required.

EIKONOGEN.—(1) The films are quicker than the ordinary, the proportionate exposure being 1 for the films, and 1½ for the plates. (2) It is not advisable to take the negatives through the film, as we have found definition suffer. (3) Colour-sensitive plates may be changed in a deep ruby light not necessarily in the dark. (4) We do not like the plates named so well as the originals. (5) Not absolutely, though nearly so. We may possibly see our way to place the second class in order of merit.

MANFIELD.—If the toning bath is acid the prints may refuse to tone, but they always turn yellow first. Pyro in the bath would cause precipitation of the gold. Add a good-sized pinch of carbonate of soda to the bath, and then try.

H. L.—There is a Surbiton Society, Secretary, A. E. Lane, Esq., The Ferns, King Charles Road, Surbiton.

H. ORMEROD.—No. 1 and 2, development not carried far enough; No. 3 and 4 both suffer from green fog, which you call yellow marks. They really are yellowish-green by reflected light. The proper treatment would have been to have bathed them in—

Ferric Chloride .. .. .	50 gr.
Potassium Bromide .. .. .	80 "
Water .. .. .	4 oz.

then developed with ferrous oxalate. Increase your P number when using the meter, you will thus increase the exposure, or else try the developer suggested by Mr. Watkins, viz.:—

Pyro .. .. .	2 gr.
Bromide .. .. .	1 "
Ammonia .. .. .	2 "
Metabisulphite of Potash .. .. .	1 "
Water .. .. .	1 oz.

This is the developer his P numbers are calculated for, or if you prefer to stick to the developer you are using reduce the alkali by half at first. Shall we return negatives.

## Sale and Exchange

### RULES.

CHARGE.—Twelve words or less for Fourpence.

Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

DEPOSITS.—The money for goods forwarded on approval may be deposited with the Publishers of the AMATEUR PHOTOGRAPHER, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

ADDRESS.—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

COMMISSION.—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

PAYMENT.—All payments are to be by cheques or Postal Orders, made payable to Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.

Bicycles, Tricycles, etc.—Safety bicycle (Success), light roadster, solid tyres, gear 60 in., all balls, cost £17; exchange for good quarter-plate camera set, or state lowest cash price with particulars.—R. Baxter, 17, Athol Street, Belfast.

Cameras, etc.—Beck half-plate square mahogany, three double backs, solid leather case with lock and key, £4, or exchange Chadwick stereoscopic camera; Blair square whole-plate mahogany long-focus camera, complete with tripod, six feather-weight double slides, new, in case, £10.—Marshall, 24, Franche Court Road, Tooting, S.W.

Half-plate camera, double extension, rack work, every movement, 32s.—Allen, Moffatt Street, Maidenhead.

Cameras, Lenses, etc.—Quarter-plate camera, square, cloth bellows, double slide, landscape lens, folding stand, hand box, printing-frame, new, 20s.; ditto, similar camera, etc., but without stand and box, 14s.; both Fallowfield's; mahogany square camera, plate 7 by 7, leather bellows, double slide, fitted half and quarter carriers, new full-plate landscape lens, sliding ash stand, capital condition, 20s.—E. Lyons (side entrance), 27, Pilgrim Street, Ludgate Hill, E.C.

For sale, a half-plate 1889 Instantograph camera, rapid lens with adjustable diaphragm and patent shutter, and two dark slides, price £2 15s. May be seen on application to H. F., 67, Downs Road, Clapton.

First-class half-plate camera, six double backs, £5 10s.; Optimus rapid Euryscope lens, £4. Seen any time by appointment.—F. Holmes, French Embassy, Albert Gate, London.

Quarter-plate landscape camera, dark slide, lens and shutter, bargain, 29s.—752, Old Kent Road.

Dark Slides, etc.—Dark slides, three half Instantograph, new, 6s. 6d. each; 7 by 5 grand rectilinear lens, stops f/8 to f/32, hood and flange, 25s.; approval.—Adams, 90, Hatton Garden.

Three Tyler's metal dark slides, with adopter and focussing screen, to fit Lancaster's quarter-plate Instantograph, 6s.—H. Hosking, 212, Lambeth Road.

Hand-Cameras, etc.—Last season's Talmer hand-camera, holds 12 quarter-plates, time and instantaneous shutter, cost £3 10s., together with six dishes, cutting shape, etc.—Edward Cottle, 3, Union Terrace, New Brighton.

Stereoscopic Company's 5 by 4 graphic hand-camera, rapid rectilinear lens, time and instantaneous shutter, plates or films changed automatically, perfect order, cost £13; take £6 10s.—Ladbury, 131, Upper Street, Islington, N.

Fallowfield's Facile hand-camera, in good condition, superior single lens, working f/11, fine definition, £2 10s.—R. M. Jones, 98, Tweedale Street, Rochdale.

For sale, a half-plate hand-camera fitted with Swift's lens, Wollaston shutter, and a rollholder, covered with Morocco leather, like new, price £10. Further particulars from F. Bradley, Raglan House, Beaumaris, Anglesey.

London Stereoscopic Company's hand-camera, quarter-plate, quite new, cost 5 guineas, price £2 10s.—No. 312, office of this paper, 1, Creed Lane, E.C.

Lantern.—Lancaster's first quality enlarging lantern for oil or gas, 9 in. condensers, good condition,

cost £11. Offers to R. T. Walker, Balance Street, Uttoxeter.

Magic lantern, Optimus, best make, mahogany body, 4 in. condensers, splendid definition, condition as new, limelight and oil lamp, cost £5, a bargain at £3.—No. 311, office of this paper, 1, Creed Lane, E.C.

Optimus three-wick lantern, condition as new, only used six times, and 40 slides—Gulliver's Travels, Egyptian War, Venice, etc.—carriage paid, 37s. 6d., cost double; suit a clergyman; trial allowed.—Heathcote, 3, Ritson Road, Dalston.

**Lenses, etc.**—Ross' No. 3 P. symmetrical, cost £3 10s., covers half-plate, 45s.; Dallmeyer 6 by 5 R.R., with Newman's shutter, cost £7, sell £4 10s.; 7 by 5 best French R.R., cost 45s., sell 20s.; Lancaster's half W.A. rectilinear (iris), cost 42s., for 30s.; Lancaster's quarter Instanto lens, new, 15s.; whole-plate camera (Watson's Premier pattern), long extension, every movement, one double slide, whole-plate Wray's landscape lens and stand, cost £12, sell £7 10s.; half-plate Lancaster's best brass-bound camera, five double slides, cost £7 10s., sell £5; mahogany revolving stereoscope for 50, cost £3 10s., sell £1 15s.; 7½ by 5 Watson's Tourist camera, three dark slides, cost £7 10s., for £3; Lancaster's half-plate Instanto set (splendid lens), £3; studio stand, good as new, cost £2 10s., sell 30s.; 21s. Griffith's detective, 15s.; 21s. Stirn's vest camera, 7s. 6d.; 15s. Jeffery print washer, 7s. 6d.; Newton's £5 5s. patent Phantasmogoria lantern, 4 in. condenser, mahogany 4-wick lamp, 60s.—Parly, 9, Cradock Street, Swansea.

Ross' 9 by 7 rapid symmetrical lens, iris diaphragms, perfect condition, cost £3 5s., price £6; Thornton-Pickard extra-rapid time and instantaneous shutter, 2½ in. hood, with speed indicator, new, fits above lens, cost 35s. 6d., price £1 5s.; Dallmeyer 8½ by 6½ rapid rectilinear lens, good condition, cost £7, price £5.—No. 303, office of this paper, 1, Creed Lane, E.C.

Whole-plate rectilinear, 11 in. focus, iris diaphragms, f/8 to f/64, movable hood, splendid lens, new, 25s.—L. & S. Kenilworth Road, Willesden Lane, London, N.W.

Ross' rapid symmetrical lens, 5 by 4, cost £4 5s., price £2 10s.; Ross' portable symmetrical, 4 in. focus, cost £3 5s., price £2 2s.; Ross' portable symmetrical, 5 in. focus, cost £3 10s., price £2 5s.; all in perfect condition.—Howard, 49, Pier Road, Eritch.

Wray's W.A. landscape lens, 9 in. focus, used twice, 28s. cash.—No. 310, office of this paper, 1, Creed Lane, E.C.

7 by 5 rapid rectilinear lens, Waterhouse diaphragms, new, 20s.; 7 by 5 rapid landscape lens, Waterhouse diaphragms, 10s.—McComas, 5, Laurence Pountney Lane, City.

Optimus portable symmetrical 7 by 5, sacrifice 31s.; splendid lens; approval.—A. Lambert, Star Street, Ware, Herts.

Quarter-plate lens, sliding mounts, post free, 5s.—J. Hill, 35, James Watt Terrace, Barrow-in-Furness.

Quarter portrait and view lenses, exchange for quarter Laverne; also AMATEUR PHOTOGRAPHER from June, '89, to date, clean, 5s.—No. 2, Osborne Villas, London Road, Buxton.

Beck's 12 by 10 rapid rectilinear, iris diaphragm, new, £6 18s.; Beck's 5 by 4 ditto, ditto, £2 15s.; Beck's 7 in. wide-angle rectilinear, new, £4 8s.—Marshall, 24, Franche Court Road, Tooting, S.W.

Dallmeyer 1A cabinet lens, £7; Dallmeyer 5 by 4 R.R. lens, £2 10s.; Ross' cabinet lens, 8½ in. focus, £7; Crouch's 10 by 8 W.A. lens, £3; pair Crouch's 3 in. wide-angle lenses, £3.—Biddle, 97, Medlock Street, Manchester.

Optimus 7 by 5 rapid rectilinear, Waterhouse stops, excellent condition, 37s. 6d.—J. H. Godding, 6, Milton Villas, Newbury.

**Rollholder.**—Half-plate Eastman's rollholder, latest pattern, 28s.; half-plate Instantograph lens and shutter, 16s. 6d.; 7 by 5 wide-angle rectilinear lens, 30s.; three-fold tripod, 6 in. top, 15s.—F., 1, Richmond Terrace, Shelton, Stoke-on-Trent.

**Sets.**—A fine 10 by 8 camera by Lawley, three double dark slides, a very fine portable symmetrical 10 by 8 lens by Ross, tripod, focussing cloth, satchel; the whole set was bought two years ago and has been little used.—Mrs. A., 24, Marville Road, Fulham.

Le Meritroire half-plate camera, lens, dark slide, tripod stand, rebounding shutter, leather case, specially made, room for extra slides, 45s.; specimen print. L., Gore Lodge, Glenageary, co. Dublin.

Lancaster's 10 by 8 1891 Instantograph camera and one double dark slide, all latest improvements, cost £5 5s., price £3 17s. 6d.; four-fold camera stand by Sands and Hunter, very rigid, for whole or half plate, cost 25s., for 12s. 6d.; quarter wide-angle lens by Ross, London (No. 14,064), with two adapters and flange, only £1 12s. 6d.; Lancaster's whole-plate Instantograph shutter, 5s.; lantern lens (no flange), 5s.; 3½ in. lantern condensers, brass mounts, 2s. 6d.; view finder, cost 5s., for 2s. 6d.; 10 by 8 air-tight glass dipping bath and dipper, best mahogany case, screw top, cost 27s., for 10s.—Hutchinson, Mercer Row, Louth.

Half-plate Lancaster's 1892 Instantograph camera, slide, tripod, and R.R. lens, bargain, 67s. 6d.; approval.—14, George Street, Stroud, Glos.

Quarter-plate camera, long extension, reversing swing back, six double slides, Optimus 5 by 4 lens, shutter, waterproof case, tripod, £5.—C. H. B., Litho, 102, Clerkenwell Road.

Half-plate set by Perken, Son, and Rayment, comprising camera, R.R. lens, three double dark slides, folding stand, in leather case, condition as new, 6 guineas.—C. White, Hillside, St. Germain's Road, Forest Hill, Kent.

Quarter-plate Instantograph, complete, with dark slide, instantaneous lens and shutter, folding tripod, velvet focussing cloth, in waterproof sling case, very little used, 37s. 6d.—H. Hosking, 212, Lambeth Road.

Lancaster's half-plate Merveilleux set, almost new, specimen print sent, bargain, 32s. 6d.—T. Hall, Artist, Lancaster.

Lancaster's half-plate patent camera (brass-bound), three double slides, rectilinear lens, leather case, focussing glass, and stand, price £6.—A. B., 166, Albany Road, S.E.

Quarter-plate outfit, complete, Lancaster's Le Meritroire, camera, lens, two double slides, tripod, printing frames, quantity of chemicals and mounts, etc., good condition, price 27s. 6d.; approval; deposit.—J. Sanderson, 13, Cort Street, Blackhill, Durham.

Lancaster's half-plate Instantograph, dark slide, tripod, fitted with rapid rectilinear lens, Optimus half-plate burnisher, splendid machine, ash studio stand with adjustment, two dishes, four half-plate printing frames, measures, cutting shapes, retouching desk, two paper backgrounds, Marion's guide, drop shutter focussing cloth, splendid condition, £6 the lot; cost double.—L. G. Harding, Nelson House, Margate Road, Southsea.

**Sundries.**—AMATEUR PHOTOGRAPHER from 5 July, '89, to 10 June, 1892. What offers? Also half-plate camera, tripod stand, almost new.—MacLaine, Hazel Cottage, Oban, N.B.

AMATEUR PHOTOGRAPHER, 320 numbers, 1888-'92, good condition, 10s.—F. C. A., Willersley, Cromford, Derby.

Photography, vols. i. and ii., beautifully bound, 12s.—63, Tressellian Road, Brockley.

Electric motor, reversible, cost £3 3s., good condition, cash 25s., or exchange to value in photographic goods.—William Hare, Photographer, Sutton, Surrey.

Assortment stoppered bottles, several excellent photographic hand-books, sale, cheap, property deceased, invaluable beginners.—Executor, 54, Orchard Place, Southampton.

**Tripod.**—Half-plate sliding tripod stand by Billcliffe, good condition, cheap, 10s., cost double; no approval.—B. S. Harlow, Heaton Norris, Stockport.

## WANTED.

**Cameras, etc.**—Old 15 by 12 square bellows camera, rackwork adjustment, and dark slide; condition no object so long as woodwork is sound. Full description and very lowest price to R. D. Smith, 14, Frogna, Hamstead, N.W.

Wanted, cheap, Underwood's quarter construction camera.—Burrows, 18, Kirkland Street, St. Helen's, Lancashire.

**Case.**—Wanted, case for whole-plate camera.—H., 24, Paragon, Ramsgate.

**Lamp.**—Ruby lamp wanted; will give in exchange good stereoscopic slides—Egypt, Holy Land, Paris, London, statuary, etc.—H. Mann, 48, Elgin Avenue, London, W.

**Lenses, etc.**—Wanted, Lancaster's combination rectilinear lens and dark slides to fit quarter-plate Instantograph; state lowest price.—J. Russell, Belmont, Uddington, N.B.

Rouch's Eureka quarter-plate, good condition. Full particulars to No. 306, office of this paper, 1, Creed Lane, E.C.

**Rollholder.**—Wanted, quarter-plate rollholder for Shew's Eclipse camera.—Nos. 309, office of this paper, 1, Creed Lane, E.C.

**Sets.**—Wanted immediately, half-plate camera, with R.R. lens, tripod, two or three double backs, and case, by good maker, in good condition and moderate price; must be sent on approval; deposit.—Logan, St. Oswald's, Tenby.

**Show Cases.**—Wanted, photographers' show cases with doors, any size, for outdoor use.—Walker, Grove Cottage, Heckmondwike.

**Shutter.**—See-Saw shutter, oblong, pneumatic, cheap and good.—Mr. Tipper, Grimston, Lynn.

**Stand.**—Wanted, studio stand for cash, must be cheap; also other accessories.—Cole, 250, Caledonian Road, N.

Wanted, portable stand for hand-camera. Full description to Leake, 76, Comeragh Road, West Kensington.

**Sundries.**—Wanted, enlarging apparatus; good 5 by 4 R.R. lens.—Parker, Culmore, Londonderry.

**Cameras! Cameras! Cameras!** Lenses! Lenses! Lenses! and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange.

Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, Corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Lenses.**—For sale, 15 by 12 Optimus wide-angle symmetrical, rotating stops, 10 in. focus, as new, take £4 15s., cost £9, cheap; Dallmeyer No. 3 D patent portrait lens, 8½ by 6½, views 10 by 8, focus 10½ rack focussing, grand article, cost £9 10s., take £6 10s.; Ross' whole-plate rapid symmetrical, Waterhouse stops, works f/8, £4 12s. 6d.; whole-plate rapid landscape lens by Tench (this is really same as Dallmeyer No. 8), rotating stops, grand definition, works f/16, will cover 10 by 8, quite new, take 60s., cost more than double; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross' atonic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; whole-plate Suter No. 8, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; cabinet portrait lens, quite new, rack focussing, Waterhouse stops, take 25s., cost 60s.; Hockin's desideratum rapid rectilinear, covers 7 by 5, iris stops, movable hood, grand article, quite new, take 32s. 6d., cheap; Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; half-plate Lancaster's Instantograph lens, iris stops and instantaneous shutter, as new, 15s.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Hand Cameras.**—Stereoscopic Company's Graphic hand-fitted, Stereoscopic Company's black band rapid rectilinear, iris stops, lever focussing, blind shutter, changing box, covered leather, £4 17s. 6d., as new; Lurzo hand-camera by Robinson, Regent Street, quarter-plate rapid rectilinear lens, time, and instantaneous shutter, finder, and leather case, carries 100 films, £4 10s.; No. 2 Kodak rapid rectilinear lens, instantaneous shutter, new spool, sixty films, covered black morocco, and in leather case, £4 17s. 6d.; No. 1 Kodak, as new, rapid rectilinear lens, instantaneous shutter fitted, 50 films, covered leather, in case, £2 17s. 6d.; Tolmer hand-camera, landscape lens, rotating stops, finder, carries 12 quarter-plates, changing bag, best condition, take 50s.; Adams' Ideal, covered leather, new few weeks since, very latest pattern, rapid rectilinear lens, carries twelve quarter-plates, two finders, etc., £5 17s. 6d.; Griffiths 4-plate magazine hand-camera, carries twelve plates, changing bag, good lens, finder, etc., 22s. 6d.; Samuel's patent stereoscopic hand-camera, rapid rectilinear lenses, changing bag, instantaneous shutter, for either quarters, cabinets, or stereoscopic, as new, 37s. 6d.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, 32s. 6d.; London Stereoscopic Company's despatch detective, covered black leather, fitted Stereoscopic Company's rapid rectilinear lens, Newman's shutter, two finders, three double slides, rack focussing, size quarter-plate, as new, take £6 6s., cost £10 10s.; Ariel hand-camera, Shew's eclipse pattern, leather bellows, quarter-plate, rapid rectilinear lens, rotating stops, Kershaw shutter, three patent Turnbull slides, quite new, take 63s. All above warranted in very finest order.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Cameras and Sets.**—Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s., grand lot, 10 by 8 camera by Morley, of Islington, thorough order, leather bellows, reverses, 3 double and 2 single slides, rapid rectilinear lens, folding stand, take £5 5s.; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; half-plate Underwood's Instanto, warranted as new, reversing back, double slide, rapid rectilinear lens, and folding stand, 75s., worth £5; half-plate Instantograph, leather bellows, double extension, Instantograph lens, two double slides and folding stand, best condition, take £2 17s. 6d.; Lancaster's stereoscopic camera, finest leather bellows, size 7½ by 4½, with extra bellows, two double slides, fitted silver ring, rectilinear lens, patent See-Saw shutter and folding stand, take £6 6s., quite new; Lancaster's stereoscopic Instantograph, as new, two double slides, 6½ by 3¼ Instantograph lenses, instantaneous shutter and folding stand, take £3 17s. 6d.; quarter-plate Le Meritroire set complete, camera, lens, slide and stand, 21s.; quarter-plate 1890 Instantograph, all latest movements, leather bellows, etc., Instantograph lens, shutter, one mahogany and two metal slides, and folding stand, 37s. 6d., all above guaranteed, finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**RILEY BROTHERS**, 5, Chapside, Bradford, to make room for their constantly increasing Lantern Trade, are selling off and declining the Photographic Outfitting. All their stock can be had at amazingly low prices. Write for lists of Cameras, Plates, Photographic Papers, Dishes, Tripods, Cards, Chemicals, and every requisite. This is a bona-fide sale.

## OUR VIEWS.

"To hold as 'twere the mirror up to nature."—*Shakespeare.*

The Editor is "At Home" on Monday Afternoons from 2 till 5 o'clock, and will gladly give advice upon all photographic matters; and on Thursday Mornings to Members of the Trade, etc., from 10 till 1 o'clock.

OUR VIEWS.—Dishonest Advertisers and the Sale and Exchange Column.

LEADER.—Over-printing.

LETTERS TO THE EDITOR.—Hints to Beginners (Forett)—The Blister Fiend (Large, Browning)—A Universal Hand-Camera (Bruno)—Our Competitions (Daly)—South London Exhibition (Levett)—The Photomnibus (Wormald).

ARTICLES.—Elementary Photography (Hodges)—A Universal Hand-Camera (Bruno)—The Theory of Development (Armstrong)—Toning Gelatino-Chloride Printing-Out Paper (Valenta)—A Holiday in Norway.

AMATEUR PHOTOGRAPHER'S TOURIST INDEX.

REVIEWS.—Fortschritte in der Photographie (Eder and Valenta)—Bromide Enlarging and Contact Printing: How to do it (Dresser)—Photographic Enlargements: How to Make Them (Wheeler).

APPARATUS.—New Field Glass Pattern Hand-Camera.

SOCIETIES' MEETINGS.—Birmingham—Leytonstone—North Middlesex—Southport—Tunbridge Wells—Woolwich Polytechnic—Fixtures.

EDITORIAL DEPARTMENT.—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

### TERMS OF SUBSCRIPTION—

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	" " 6s. 6d.....	" " 13s. 0d.
OUT OF POSTAL UNION ..	" " 7s. 9d.....	" " 15s. 8d.

TRADE ADVERTISEMENTS are received up to Tuesday morning.

PUBLISHING DEPARTMENT.—All letters containing Subscriptions, Orders, Remittances, SALE AND EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZELL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE AND EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

We regret to state that we have another case of dishonest practices in connection with our sale and exchange columns, with evidence from two victims. The practice seems to be to obtain the money for goods, and then dilly-dally about, if threatened, to protect himself under the plea of having given a bill of sale to his sister, and then if anything is said about legal proceedings, our friend immediately assumes an air of injured innocence and declares he will prosecute for malicious prosecution, etc. The matter has been placed in the hands of the police, we are glad to say, so that it is quite possible that

Mr. Greaves *alias* Groves, *alias* Graves, *alias* Buckley, electrician, etc.,

Brown Lodge,  
Smithy Bridge,  
Rochdale or Manchester;

or of

75, Halifax Road,  
Littleborough;

or of

Church Street,  
Halifax Road,  
Littleborough,

may be brought to book.

We can only once more request our readers in all cases to insist upon the deposit system, no matter how trifling or trivial the amount may be. It is unfortunate that no sooner has a certain scheme been devised which may be useful to our readers, than it seems necessary to devise a protection against the swindlers who will take advantage of it.

We have received notification of dark-rooms being available for visitors at Mr. T. L. Waterman's Photographic Store, High Street, Shanklin, Isle of Wight, where may also be obtained plates, chemicals, and all the usual requisites, and at the Hillganden Hotel, Mill Street, Bideford.

The *Photographic Quarterly* for July will be published next week, and will contain a fine Woodbury gravure frontispiece from a negative by Mrs. S. Francis Clarke, of Louth, entitled "Jilted." The articles include: "On Developing Pictures on Printing-Out Chloride of Silver Emulsion Papers," by Eder and Valenta; "Life on the Broads," by E. J. Humphery (illustrated); "Recent Improvements in the Manufacture of Oxygen Gas," by C. J. Leaper; "Some Points in Exposure," by Alfred Watkins; "Camera Pictures and their Critics," by H. Maclean; and "Art Studies," by Dr. Alfred Paterson.

"Amateur Photographer" Monthly Competition No. 38.—"INLAND SCENERY WITH OR WITHOUT FIGURES." Latest day, July 25th.—Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in AMATEUR PHOTOGRAPHER Supplement, August 19th.)

## OVER-PRINTING. •

It is curious in looking over a set of prints sent in to one of our competitions to find what erroneous ideas some of the competitors have with regard to printing and toning. Certainly we do not exaggerate matters when we state that at least seventy-five per cent. of the prints are spoilt either by the use of an unsuitable printing process, or else by over-printing.

This fault of over-printing has been brought very forcibly to our notice lately, and, in fact, when discussing the question with one competitor, whose work we had condemned for this reason, he said, "Well, I can't see you're right; you say there is no sunshine in the print, yet there are distinct shadows cast by the sun." Because there were shadows our friend argued there must be sunshine, never recognising the fact that it was possible to so degrade the high-lights as to destroy all brightness and brilliancy.

To calmly consider all the causes which lead to this result would, we are afraid, absorb more time than we can possibly spare, but first and foremost, and we are sorry to say the most general cause, is profound ignorance as to what is and what is not sunlight. It seems to be the idea of some workers that having obtained the negative they can do no more in influencing the picture, whereas really the making of the picture lies in the printing more often than one would suppose.

In sending in a print for competition, it is almost wise to print from the negative in as many different printing processes as we can command, and then having obtained the assistance of some friend who actually does know something of photography, as to deciding which process renders the best print, to try and see how far we can doctor this up.

Whether by shading certain portions, or printing in a very subdued light, we cannot improve the contrasts generally. If a strong, hard negative, we may even print in the sun without fear; again, we can sun down a little obtrusive bit of white, or fetch something out of it by concentrating the light by a focussing glass or our special pet rectilinear, though it is hardly wise to put this to such a test.

One or two things certainly have contributed most markedly to the inferior quality of the prints, and yet each or all of the things to which we refer are in themselves advancements or improvements in their own particular branch. For instance: Hydroquinone is certainly responsible for exaggerated contrast between the high-lights and the shadows, and this merely because it is not rightly used. Eikonogen is to blame for loss of sunlight, brilliancy, and general flatness, because development is not continued long enough. Gelatine-chloride paper gives rise to uneven toning, over-toning, and generally poor results.

Now it is unfair to saddle either one of these articles with the faults, but if they hadn't been introduced we are quite sure so many of our competitors would not take us to task for finding fault with their work. Let us take gelatine-chloride paper for instance: there are at least ten or eleven different commercial varieties on the market, and from these we can obtain almost any desired effect we want without trying the collodio-chloride papers, from a high polished rich in contrast to a matt-surface, poor in contrast or soft print, and this by normal printing. By dodging, over and under-printing, we can get all sorts and conditions of prints.

We shall hope to see our readers pay a little more attention to this particular branch; it is almost better to under-print than over-print, the latter being the cause of half the miserable specimens of work we now receive in our competitions.

## Letters to the Editor.

## HINTS TO BEGINNERS.

SIR,—On the invitation of your contributor "Novocastrisensis," I will, with your permission, note one or two of the misleading statements in his article on the above.

The inaccuracy of the statement regarding the hypo solution lies in the words, "should the solution not be quite saturated," which implies that saturated solutions are not liable to the surface-attenuation referred to. I do not think the dealer's explanation of the cause of failure with the toning solution is correct. I cannot imagine that a variation in the strength of the gold solution, so infinitesimally small as that brought about by the condensation of water on the sides of the bottle could account for so disastrous results. Each time the gold was used, the solution, by the mere handling of the bottle, was rendered practically uniform. Diffusion is constantly going on between liquids of different specific gravities, provided the liquids are in contact and miscible with each other. In using a few drops of solution of gold chloride, how does your correspondent know that he always uses the top layers?

"Novocastrisensis" produces prints to show that his "rough-and-ready" method of compounding a fixing bath is at least efficient. By practice he has found out "how to do it," but I am afraid he has failed to convey the information to your readers.

For a toning bath, the writer makes a solution of borax, 12 gr. to 1 oz., and for use he dilutes it with an equal quantity of water. Solution of borax is stable, and could be made of the required strength at once, and so save double measuring. He says this solution may test acid. Borax is an alkaline salt, and its solution cannot possibly give an acid reaction. I have used the borax bath when of a deep port-wine colour, and have no experience of the slow action referred to in the article.

The only other point to which I will refer is the use of hot water for making solutions. Both toning and fixing solutions are directed to be made with hot water, the latter *boiling*. When the uninitiated, for whom the article is especially intended, comes across such directions, he naturally concludes that the prescribed temperature, being italicised, is a *sine qua non*. All solutions up to saturation point may be prepared with cold water. For most purposes the salt may be put into any convenient vessel, water added, and solution promoted by an occasional shake or stir. For large quantities it is convenient to tie the salt in a muslin bag and suspend it in the water, when solution will take place without any further attention. Why are contributors of photographic formulae so fond of hot water? I have seen a formula directing ferrous sulphate to be dissolved in boiling water, which decomposes the salt to a considerable extent, and is quite unnecessary.—Yours, etc.,

J. G. FORETT.

## THE BLISTER FIEND.

SIR,—Though somewhat late, I beg to thank those gentlemen who were kind enough to suggest a way of escape from blisters. But the only one that I had not tried was that recommended by "John Browning." Had I answered at all, my best thanks would have been due to that gentleman, as, with a paper most fearfully prone to blisters, I did not have the minutest fiend. I see Mr. Browning is hauled over the coals this week, but perhaps your correspondent "P." used a bad or adulterated sample of methylated spirit. I was fortunate enough to get the very best of purple tones. I have also tried the same paper using the spirit differently, as immersing the prints in the spirit *before* toning renders the paper transparent, so that one cannot well see the exact shade at which toning has arrived. Therefore I do not use the spirit until just before going into the fixing solution. I give them a fair rinsing after toning, then immerse in the spirit for from five to ten minutes, then fix in the usual way, then wash thoroughly. Although up to the present the spirit has done its work well, *i.e.*, preventing blisters, I am sorry to say it took all the pink tinting out of the albumen (which pink tint is much liked by some), whence my dislike for having to use any preventive, and as the correspondence under the above title has elicited from more than one the fact that it is quite possible to manufacture a paper that cannot be made to blister it is to be hoped we may look forward to the time when the makers of blistery paper shall be looked upon as photographic sinners. I would respectfully suggest that "P." should give the spirit another trial, being careful to see that each print is not unequally soaked

in the same, or, of course, patches would be the consequence. But whether the same treatment, for papers of different make, will act in the same way I cannot yet say, and I do not *know* if the spirit affects in any way the permanency of the prints. I should not *think* it did.—I am, sir, yours truly,  
H. S. LARGE.

SIR,—I am sorry "P" has made such a mess of the spirit cure which I advised for blisters. He must have used the stuff sold under the new excise regulation containing mineral oil, when, of course, one could not reasonably expect water to act on places where the oil had taken effect.

As to the flatness complained of, he must certainly look elsewhere than the spirit for the cause. Did he wash thoroughly after saturation with spirit? Because the free silver takes longer to eliminate.

I still claim that my treatment with spirit is a sure cure, but the spirit must be good, which I distinctly stated in my advice. Also the operations in connection with this treatment must be conducted with intelligence, or one may expect to get prints as flat as oneself.—I am, yours, etc.,  
JOHN BROWNING.

8, Longfield Avenue, Blackhorse Road, Walthamstow.

\* \* \* \*

#### A UNIVERSAL HAND-CAMERA.

SIR,—Your correspondent "H. E. H." is correct in stating that when viewing G from the back, the image, though direct, is inverted. But when the camera is held to the right side, and the finder is viewed from above, it is easy to judge of the picture as it will appear on the plate, the right way up. A bi-concave lens gives a direct image the right way up. To obtain the same result by reflection, a second mirror is, of course, required, and might be hinged to fold flat when not in use. But "H. E. H." will find, as I did, that the angle at which the second mirror must be placed renders it most difficult to see the image at all.

If the bi-concave lens is secured to the top of the camera, and viewed in a horizontal direction, the camera must be held under the chin, a position awkward, conspicuous, and by no means conducive to steadiness. The finder, as described, is simple and effective.—I am, yours, etc.,  
W. H. B. BRUNO.

\* \* \* \*

#### OUR COMPETITIONS.

SIR,—In your last issue you mention a suggestion from a correspondent to limit your competitions to "one particular plate, one lens, one kind of printing-paper, giving each a turn." In my humble opinion this is a most mischievous proposal. The chief object of your competitions is, I take it, to teach your subscribers to turn out *pictures* by means of photography, not to make them good *machinists*. If you fall in with this proposal you will next prescribe the developer! Photography has often been stigmatised as a purely mechanical art, and I venture to think that if you follow your correspondent's advice you will do something to justify the taunt. I trust that in the future, as in the past, you will judge by results, leaving each competitor free to choose his tools. Should he select an unsuitable lens, or a printing process which does not do most justice to his subject, that is his lookout, but don't wrap your competitors in swaddling clothes. Your correspondent's suggestion is a good one from the optical instrument maker's or from the plate maker's point of view, but regarded from an artistic stand-point it is detestable.—Yours, etc.  
Italy.  
H. DE BURGH DALY.

\* \* \* \*

#### S. LONDON EXHIBITION.

SIR,—Lest any misapprehension should arise from the opening sentence in your paragraph of last week respecting a South London Exhibition, I should like space to say that our committee not feeling that sufficient enthusiasm had been aroused by their proposal (namely, that a joint exhibition of the various London societies south of the Thames be held next autumn in place of the usual local series), have, for the present at least, decided to take no further steps in the matter.

As the next best thing, however, I should like to see the scheme of the South London Photographic Society well supported by the members of the neighbouring clubs.—Yours, etc.,  
Brixton Camera Club.

FRED. W. LEVETT (Hon. Sec.)

#### "THE PHOTOMNIBUS."

SIR,—Twice your printer has made a little addition to the spelling of our word "Photomnibus," which is intended by us to mean photos or photography for all. The addition of an *o* makes it Photo-Omnibus, which might be taken to mean a "Bus" fitted as a dark-room, which we need scarcely say we do not build, nor indeed would our popular price, 2s. 6d., enable us to undertake so large an order.—Yours, etc.,  
WORMALD AND CO.  
Sutton, Surrey, July 5th, 1891.

## Elementary Photography.

By JOHN A. HODGES.

### CHAPTER XXIII.

#### FLASH-LIGHT PHOTOGRAPHY.

Probable Origin of the Flash-lamp—Capabilities—Flash-lamps in general—England's Lamp—How to connect several Lamps and Fire them simultaneously—Arrangement of the Lamps—Home Portraiture—Focussing, an alternative method—Gun-cotton and Magnesium—Drawbacks—Necessary Precautions—Flash-mixtures, dangerous nature of—Taking Dark Interiors—A Difficult Subject, how taken—Development.

If powdered magnesium, or magnesium dust, be forcibly blown through a flame a rapid combustion of the metal takes place, and the result is a brilliant flash of light. Various other substances, in themselves non-combustible, may be made to ignite in the same way. Indeed, the flash-lamp of to-day was probably suggested by the old-fashioned plan of producing stage lightning by blowing powdered lycopodium through a flame. The light produced by the magnesium flash is sufficiently actinic to permit of a photograph being taken with it, and, indeed, if a little trouble be taken, most excellent results may be obtained. The exposure

FIG. 1.

FIG. 2.

being practically instantaneous, the sitters can be taken in an ordinary room, and whilst engaged in ordinary occupations in natural attitudes without fear of movement.

A great deal of ingenuity has been expended in the construction of "flash-lamps," as the apparatus used in producing the light is called, and the reader will find in the shop of any dealer in photographic materials quite a bewildering assortment from which to choose. It is not my intention here to describe in detail the merits or demerits of the different forms of lamps. Some, no doubt, are more efficient than others, but a suitable lamp should be easily procurable for about 4s., or even less. The general principle of construction is the same in all lamps, that shown in fig. 1 being the invention of Mr. England: A is a metal chamber, upon the top of which a wad of felt, which has been saturated with methylated spirit, is placed; B is a tube in which the magnesium powder is placed, about ten grains being sufficient. The tube B comes out at C, and is there connected, by means of a piece of india-rubber tube, with a collapsible india-rubber ball. Upon smartly squeezing the ball the air-pressure drives the magnesium powder

through the flame, producing an elongated flash of great brilliancy.

It is difficult to get the best effects of lighting with only one lamp, and much better results will be obtained if two, or even three, are employed. It will, of course, be necessary to so arrange matters that the three flashes shall be simultaneous, but this is by no means difficult to do. Supposing three lamps are to be employed, a prong-shaped piece of tube must be procured of the shape shown in fig. 2. The lamps are connected by lengths of tubing to 1, 2, and 3, No. 4 being connected by means of another piece of tubing to the pneumatic ball arrangement, or better still, when several lamps have to be fired simultaneously, to a pair of ordinary bellows.

The general directions given in the preceding chapter upon indoor portraiture apply equally when the exposure is made by flash-light, and, therefore, it will not be necessary to repeat them again here. The most important matter to be attended to is the arrangement of the lamps. The object to be aimed at is to get a good soft lighting, which will bring out the features in well-modelled relief. This, as I previously mentioned, it is difficult to do with one lamp, and the most suitable disposition of the lamps and sitter

Plan of Room  
FIG 3

may best be shown by the aid of a diagram. In fig. 3, A represents the sitter, or sitters, B being the camera, and C, D, E, the three lamps. These must always be either behind the camera, or at any rate screened from the lens, and well out of its field, or hopeless fogging of the plate will result. If the lamps are placed close together a hard unpleasant lighting with heavy shadows is likely to result, but by placing them in the position shown in the diagram, an artistic effect should be produced. The great advantage of this system of lighting over ordinary daylight is that the sitters may be placed in any desired part of the room, and one is not hampered with any such considerations as getting the most suitable lighting from the window. Very natural and pleasing pictures may be taken in this way, but much will, of course, depend upon the artistic ability of the operator.

Focussing presents some little difficulty. It is useless to attempt to focus the sitters themselves. The best plan is to place a lighted candle on the seats which they are to occupy, and sharply focus that. The candle being removed the sitters may then be carefully posed, when, if the lens is a reasonably good one, it will be found that they will be quite sharp in the resultant negative. The lamps should not be placed too low down, C and D should be about five

feet from the ground, E being about three feet. The combustion of the magnesium results in the production of a dense cloud of white smoke, oxide of magnesium, this subsequently settles in the form of a very fine powder, but will not cause the least damage to furniture. It is advisable not to make a second exposure until the fumes from the first flash have entirely disappeared. Many people disregard this caution and then wonder why they get fogged, flat negatives.

Flash-light photographs may be produced without the aid of a flash-lamp by the following method. A tuft of guncotton, weighing about six grains is loosely spread out on a piece of sheet tin, or on the back of an ordinary tea-tray, and its surface sprinkled over with powdered magnesium, from fifteen to twenty grains should be sufficient. This may be placed on the top of a pair of steps, and ignited by means of a long wax taper. This method is almost as effective as the lamp, the chief drawback being the great amount of smoke that is produced, which although perfectly harmless, causes a very unpleasant effect when inhaled. Guncotton being a very explosive substance when compressed, should not be tightly packed in the tin or vessel containing it, and should only be stored in small quantities.

A third method of utilising the magnesium light for photographic purposes is by the use of what are known as flash powders. All mixtures of this class are of a highly explosive and dangerous nature, both in their use and in their preparation, and I strongly advise the reader not to attempt to either make or use them. I shall therefore not give any formula for making them in "Elementary Photography."

Flash-light photography affords a means of securing photographs of dark interiors which it would be difficult, if not impossible, to secure by other means. As an instance of what may be done in this direction, I may refer the reader to the illustration, and which represents the interior of a wine vault in the City to which the light of day has never penetrated. The exposure was effected by burning a large quantity of magnesium and gun-cotton in the manner already described, assisted by an auxiliary flash-lamp, two assistants standing in recesses in the wall, also burning long strands of magnesium ribbon.

Two negatives were taken, both of which proved fairly successful.

I have said nothing about development, for it usually presents no special difficulty, the plates, as a rule, being fully exposed and coming up without forcing. The only practical difficulty in taking flash-light portraits is in avoiding flatness on the one hand and hardness on the other. This being overcome the rest is plain sailing.

## A Universal Hand-Camera.

By MAJOR BRUNO.

(Continued from page 477.)

### CHAPTER V.

THE interior camera consists of the "back," or frame to which the dark-slides and roll-holder are fitted, conical bellows, a lens-board, and the stage which carries the latter. No base-board is required. It is not intended to describe the manufacture of dark-slides in these articles, directions having already appeared in the pages of this journal. If the amateur is not sufficiently skilled in wood-working to attempt their construction, he is advised to

have them made to fit the camera, of the *block* (not book) form, and with the shutters to draw right out. Messrs. Braine and Sons, 22, Bedford Terrace, Moray Road, London, N., make slides of this description, very compact, and suitable for the camera, at about 4s. 6d. each. If a roll-

FIG. 11

holder is to be used, care should be taken when fitting it to the camera that it is exactly the same "register" as the dark-slides, *i.e.*, that the sensitive surface of the film is the same distance from the lens as that of the plates in the slides.

Fig. 11 shows in detail the back of the camera, with the dimensions recommended. The frame-work is made of quarter-inch stuff, dovetailed together and assisted by fine brass screws. To the front of this casing a frame F is firmly glued, and a narrow strip of black velvet should be let in for half its thickness, from V to V, to exclude all light when the dark-slide is in position. The whole of this frame-work, and the front F, must be perfectly true, and squared up in all parts, as upon this the correct fit of the dark-slides, etc., depends. R R are runners of sheet-brass, screwed to the top and bottom of the frame-work, and turned over at right angles for one-eighth inch. A groove being cut along the sides of the dark-slides they run upon these brass strips, and are at the same time passed

FIG. 12

close to the frame F. Careful fitting is equally required here, to ensure ease in inserting and withdrawing the dark-slides, at the same time excluding all light. At B and B' bushes are screwed in (of the usual camera pattern) to

take set screws, the use of which will be seen when describing the swing arrangement. At T, a small screw turn-hook is fixed, to lock the dark-slide in place when withdrawing the shutter.

Having now completed the back itself, glue to the *inner* side of the frame F the large end of your conical bellows. These should possess a draw of about 8 in., and may be of either cloth or leather. If not made at home they can be obtained from Mr. Park for a small sum. To fit our camera, the large end should measure externally 5 in. and  $4\frac{1}{2}$  in., and the small end  $3\frac{1}{2}$  in. and 3 in. The front or lens-board to which on the inside the bellows are to be glued at their smaller end, and to the other side of which the lens flange is screwed, is shown in fig. 12.

It should either be made of  $\frac{1}{4}$  in. stuff, framed up, or of two thicknesses of  $\frac{1}{8}$  in. wood, glued together in opposite directions of the grain, as precaution must be taken here also against warping. The aperture A must be cut out with a fret-saw, or centre-bit, to take the lens flange, and all lenses used should fit this flange, by means of adapters or otherwise. If a bayonet-catch flange can be used, so much the better. Why lens makers continue to turn out their productions with the slow and troublesome screw flange, is one of the many photographic conundrums. At B and B' two more bushes for set screws are to be fixed.

FIG. 15

It may here be noted that all wood work should be smoothed, and all screws filed down flush, and finished off with sandpaper as the parts are finished. It must be left to the makers' judgment to what extent he may polish or otherwise complete the various parts. But the interior to the box, the frame F (fig. 11), and the side of the "front" (fig. 12), to which the bellows are glued, should be left dead black. A suitable material to apply for this purpose is made by mixing a little dry lamp-black in French polish.

It dries quickly, a good matt black.

Having now completed the small camera, proceed to make the stage which carries the front to and fro for focussing. This consists of a base-board M, two inches broad, and of such a length from W to W that it will just slide along the bottom of our box, in grooves as shown by the dotted lines. This base-board must be so made that it will remain true, and need not be of thicker material than a quarter inch if framed up to prevent warping. K is the bush into which the clamping knob shown in fig. 5, p. 435, screws. The uprights which hold the "front" (fig. 12), and give the necessary rise and fall, are made of strips of half-inch stuff Y Y, with a rabbet cut in them as shown to take the "front," the thickness of which, we have seen, is  $\frac{1}{4}$  in. These strips should be morticed into the base-board M, and further secured by stays, T, of sheet brass. L L are pieces

of sheet brass  $\frac{1}{2}$  in. wide, with a "toe" turned up at right angles to their face. This toe is screwed to the base-board M, and the strips L L are also screwed to the wood uprights Y Y, on one side as in sketch. It will now be seen that the camera front (fig. 12) slides up and down in these uprights, and is clamped at any point by the set screws (vide dotted lines), working in slots s s, which must be filed out of L L. The result of this arrangement is a rigid stage which carries the lens-board to and fro for focussing, while at the same time it gives a rise and fall motion sufficient for all purposes. The grooves in which this stage runs are formed by screwing strips of wood to the sides of the box, and they should be fixed after the stage is placed in its position, so that a good fit can be obtained. The focussing screen will not present any difficulty. It is merely a frame of  $\frac{1}{4}$  in. stuff made to fit the camera back, and to run on the brass strips R.R. (fig. 11). The dimensions are shown in fig. 15. A piece of finely-ground glass is let in flush with its outer face, and is secured by turn buttons. As already explained, the register of this focussing screen must exactly correspond with that of the dark slides and roll-holder.

(To be continued.)

## CHEMICAL PROCESSES IN Toning Gelatino-Chloride Print- ing-out Paper

IN THE COMBINED BATH.

BY E. VALENTA.

(Continued from p. 13.)

A more favourable toning action than with the above described reactions is obtained by using the lead toning and fixing baths.

I prepared a solution of

Solution of hypo, 25 per cent. ... 50 parts.  
nitrate of lead 10 per cent. ... 50 "

This solution was filtered, and then formed a colourless solution, which quickly fixed and toned gelatino and collodio-chloride prints. The colour of the print when dry is very similar to prints treated with a gold toning and fixing bath, and this method of toning is more advantageous than that by using the alum toning baths; probably the toning here also depends upon a sulphurisation of the image, but which in which case proceeds very regularly. The procedure in the lead toning is, according to my numerous experiments—

1. The lead salt, nitrate or acetate, is decomposed when mixed with aqueous solution of hyposulphite of soda, and hyposulphite of lead is formed.

The hyposulphite of lead dissolves in excess of hypo with the formation of the double salt,  $\text{PbS}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3$ ; the solution takes place especially freely in the presence of acetate salts.

2. The solution absorbs, by fixing, silver salts from the emulsion film, which form hyposulphite of silver and soda with the hypo.

3. The hyposulphite of lead is only slowly decomposed with the separation of sulphide of lead.\*

The sulphuric acid set free in this reaction reacts on further quantities of hyposulphite of lead, and sets free hyposulphurous acid, which in its decomposition acts as a toning agent, since it causes a sulphurisation of the image.

The aqueous solution of nitrate of lead always deposits sulphide of lead by longer standing, and is decomposed according to the above equations. If one adds sulphocyanide of ammonium, or potassium, to the solution, and filters, a clear colourless liquid is obtained, which also easily tones chloride prints, and which does not spoil so quickly as the lead and hypo solution.

Sulphocyanides increase therefore in this case also the keeping power of the combined toning and fixing bath.

If a solution of hypo in water is mixed with a solution of chloride of gold, hyposulphate of gold and soda (sodium auro-thiosulphate), chloride of sodium and tetrathionate of soda, according to the equation:—

Hyposulphite gold salts were used by Le Gray for toning silver

\* The sulphide of lead is immediately decomposed into sulphide of silver.

prints; the sodium auro-thiosulphate is a tolerably stable compound which is not decomposed by dilute acids (Fordos and Gelis). It is decomposed by finely divided silver by the precipitation of gold and formation of hyposulphite of soda and gold. Since the commercial chloride of gold generally has a tolerably strong acid reaction, a decomposition of the hyposulphite of soda takes place when it is used, which causes as sulphurisation of the silver, also at the same time a toning.

So far as regards the action of the sulphocyanides in combined toning and fixing baths containing gold, they are undoubtedly, in the first place, fixing agents; then these salts act against the quick decomposition of the hyposulphite compounds, and conduce, as already mentioned, to a greater keeping power of the combined toning and fixing baths prepared with them.

The action of any combined toning and fixing baths, which for the most part consist of hypo, sulphocyanide, lead salts, chloride of gold and alum, or citric acid, which substances, as will be seen from the above table, are in most of the usual combined baths for chloride of silver emulsion papers, is explained from what has been said as follows:—

(1) As fixing agents act the hyposulphite of soda and sulphocyanide salts. These latter give when used with chloride of gold alone, as toning baths, frequently, prints which show different tones and are insufficiently fixed. With hyposulphite of soda and gold salts used simultaneously these disadvantages are avoided, and good fixation and agreeable tones are obtained. Sulphocyanides further make the toning and fixing bath more durable and prevent the quick decomposition of the hyposulphite compounds.

(2) Acids, especially citric and acetic acids, act by decomposing the hypo, and thus give rise to the formation of sulphide of silver in the image.

(3) Alum and lead salts act in a similar manner; here also the toning process acts principally by the conversion of the silver image into sulphide of silver.

Alum has besides this the necessary result of hardening the gelatine film.

The lead salts act in that they combine with the hyposulphite of soda. The hyposulphite of lead formed dissolves in excess of hypo, and this solution acts, by its slow decomposition, according to the above equations, as a toning agent, in consequence of the sulphurisation of the silver image. The greater the proportion of lead in the solution, the quicker the toning and the deeper the tone obtained.

(4) Gold salts act in the combined bath by the formation of hyposulphite of gold and soda, which directly combines with the silver of the image, which silver goes into solution and gold is precipitated on the image. If also lead or alum is also present in a toning bath, sulphur toning induced by these substances takes place.

### THE ACTION OF OZONE ON VARIOUS TONED IMAGES.

Respecting the permanency of different images, experiments were instituted by exposing the same to damp and air containing ozone.

By this it was proved that prints on collodion or aristotype paper which have been toned by the aid of acid or alum, and hypo fixing solutions, possessed the least permanency, as even after two hours they appeared grey and yellowed.

Considerably better results gave the prints toned with nitrate of lead and hypo solutions; they withstood almost double as long and were not so strongly yellow as the former.

Gold-toned images behaved best in ozonised air, and, indeed, ordinary gold-toned albumen prints and pictures on celloidin and aristotype, which have been toned and fixed in pure hypo and gold baths, even after six hours, action they had, indeed, lost a little in warmth of tone, still showed, however, a photographic tone.

As a generally useful toning and fixing bath, the following may be recommended from these experiments:—

Water ...	...	...	...	...	500 parts.
Hyposulphite of lead ...	...	...	...	...	200 "
Sulphocyanide of ammonium ...	...	...	...	...	25 "
Nitrate of lead ...	...	...	...	...	10 "
Alum ...	...	...	...	...	20 "

The hypo should be first dissolved in the water, the sulphocyanide added, then the alum, and finally, the lead nitrate dissolved in a little water, the whole heated to 50 deg. C., allowed to settle, and before use 7 to 8 parts of a 1 per cent. solution of chloride of gold added to every 100 parts of this concentrated bath, and 100 parts of water. The bath will keep, and works very satisfactorily. Collodion prints should not be washed before toning and fixing; gelatine prints should be washed for a short time with pure water, and then immediately placed in the combined bath. To dilute the concentrated bath, old dilute gold baths, which contain little or no gold, may be used with advantage. — *Photo. Corres.*

## A Holiday in Norway.

PHOTOGRAPHY AMONG THE FJORDS.

(Continued from page 11.)

### III.—THE GEIRANGER AND HJORUND FJORDS.

#### THE SEVEN SISTERS.

MOST of those who had been to the Mangefos the night before knew nothing the next day till they were well on their way up the Geiranger Fjord, having passed Molde and Aalesund again while lapped in blissful slumber. Whether the trip was so arranged, or whether it was the cumulative effect of the magnificent scenery, it would be difficult to say; but each day the fjords appeared to get grander, and in every fjord the height of admiration seemed to be reached, only to be eclipsed by the scene visited on the next day and in another fjord. Still for those who have once seen it, the Geiranger will always remain a name to charm with. It is a fjord of sudden surprises, of towering hills and wonderful waterfalls. The great cliffs rise sheer out of the water four or five thousand feet in the air, and their grandeur is greatly enhanced by the narrowness of the fjord. To all appearance—though in Norway, especially, appearances are deceptive—it cannot be more than a quarter of a mile from shore to shore at places. Between these giant hills, then, whose beetling brows threatened to close in and crush the rash vessel

#### THE MOUNTAINS OF MEROK.

Along this fjord especially our photographers were busy. The ship had perforce to proceed very slowly, and the waterfalls could not be resisted. Men even gave up their lunch to get on board and try a shot at an exceptionally fine *fos*, and the Seven Sisters had to bear the brunt of a whole battalion of cameras, both of the ordinary and of the detective kind. But all the sharp, sudden corners were safely passed at last, and at the end of the eastern arm of the fjord we anchored off the hamlet of Merok. Merok itself is nothing, but its surroundings are of what the guide-books call "unsurpassing grandeur." Down through the village itself, starting from far up the mountain side, thunders a foaming cataract into the fjord below. This is the *Storfos*, and there are few finer falls to be found in the country. The actual volume of water must be enormous, and the effect is heightened by the rich colouring of the mighty hills around, and the tender flowerets that spring in the damp verdure on the water's brink all down the course of the fall. At Merok we first made acquaintance with a *sæter*. Climbing up the steep zigzag that leads to *Udsigten* (the view), we noticed a side path leading up through hilly fields and mountain woods to some huts far up the steep. These, we found, were the *sæter*, or mountain farm dairy. A rough and toilsome path showed the way up which the cattle are driven to feed on the higher pastures when those below fail. Fancy fetching the milk for one's morning coffee down from a dairy two or three thousand feet in the air! From *Udsigten* a magnificent panorama of mountain scenery is, indeed, to be

ORSTENVIK, FROM THE FJORD.

that had ventured to pass between them and even to awake their echoes with its steam whistle, the *City of Richmond* slowly moved on its way to Merok. Many a time it seemed as if the next corner could never be rounded; yet it was safely passed, and gradually the feeling of awe that had been impressed upon us wore off, and we were able to note more closely the myriads of falls that silver-veined the valley's sides. White as the snow from which they came, they leaped and slipped and drifted and plunged down the rocks and through the firs, some idly wasting themselves in mist, dissipating themselves in air because of the height from which they fell; others rolling rapidly and falling musically into the still deep waters of the fjord, and others again quietly stealing by zig-zag ways from ridge to ridge and sparkling through the trees. The lines in "The Lotos-eaters" were irresistibly recalled—

"A land of streams! Some, like a downward smoke,  
Slow-dropping veils of thinnest lawn, did go;  
And some through wavering lights and shadows broke,  
Rolling a slumbrous sheet of foam below."

And again,

"the slender stream  
Along the cliff to fall and pause and fall did seem."

Finally the *Syv Sostre*, the Seven Sisters of incomparable loveliness, were reached, the sun falling full on their silver tresses and giving them a dazzling brilliancy that almost took one's breath away.

obtained. The Geiranger Fjord seems to end in a stupendous amphitheatre of hills. All round the vast circle the snowy summits rise, dark crags piercing through the maiden snows that cover all the hollows, and standing out in rugged splendour against the blue of heaven, while the lower slopes are covered with ash and hazel and feathery birch, and the lichen-covered rocks glow in the strong sunlight with a thousand tints of grey, and brown and gold.

#### FROM SÆBO TO ORSTENVIK.

From Merok we returned through the Geiranger, but at night this time—though there were many who stayed on deck for a last look at the loveliness of the Seven Sisters—and entered the long and narrow Hjørund Fjord, anchoring off Sæbo. There is a magnificent drive from Sæbo to Orstenvik, right across country, combining the delights of steeplechasing and tabogganing with the pleasure of bowling along at a handsome pace through a charming pastoral valley, enclosed by wild cliffs and wooded hills. This drive of nearly twenty miles most of us took, the boat meanwhile going round to Orstenvik by way of the Vartdal Fjord. The road was generally very good, but it would be well for nervous people to get out and walk at many points along it. For those who can forget danger, and trust in the ponies' sure-footedness, there is a glorious exhilaration in flying down a sharp descent with a precipice on one hand going down hundreds of feet into the lake below, and birch clad hills soaring far up into the blue on the other. The earlier part of the road,

from Sæbo to Vatne, lay through softer scenery than we had yet seen, the broad green valley,

"looking to the South and fed!  
With honey'd rain and delicate air,"

opening out in many a winding vale and meadow, watered by rippling streams from the purple hills. On these the eye dwelt gratefully, resting awhile from the strain of grasping the mountain peaks. But after Vatne, and for almost all the rest of the way to Orstenvik, the *stolkjærre* rushes over the shoulders of the hills, and bumps over bridges and sweeps along by the brink of the stream, till it subsides into respectability, and suddenly enters Orstenvik by a good and level road. Orstenvik furnished us with many pleasant memories. It would be a charming place to make use of as a holiday centre, and Herr Svendsen's hotel is of the best Norwegian type. It was here that a conspicuous instance of Norwegian honesty came under our notice. A sovereign was accidentally left on the table by one of the passengers in payment for a cup of coffee, and forgotten. The next day it was returned to the Captain, though many a mile had to be traversed to do so. But the Norwegians, as a rule, are the finest peasantry in the world, utterly unspoiled as yet by the tourist, and full of sturdy independence and frank courtesy. We went into one of the houses here and saw the women making and baking the national *flatbrød*, thin circular cakes of dark colour, but by no means unpleasant flavour. They laughed heartily at our broken Norse, so heartily that the cakes were forgotten and burned, and, fearing Alfred's fate, we took our departure, and visited the church, prettily built of pine wood and grey stone, and painted white. Looking closely at the walls, it was evident that they, as well as the bridges we had noticed before, were quite innocent of mortar or cement. The stones were simply laid one upon the other, and so carefully were they chosen, and so nicely fitted that the structure stood perfectly solid and firm.

#### MEMORIES OF ORSTENVIK.

In one of the little shops near by an observant member of the party spied some conversational sweetmeats with Norwegian mottoes of tender and amorous significance printed upon them. A purchase was at once made for a few *ore*, and great was the fun that ensued. "Are you engaged?" may be a very blunt and rude question in English, but who could complain of the caressing tenderness it assumes in Norwegian, "*Er de forlovet?*" There is hardly the same grace about the look of "*Smoke pige, bliv min!*" it is true, but the actual pronunciation may be made to very prettily express the entreaty "Be mine, sweet maid." About "*Giv mig et kys!*" there can be no mistake, and evidently the maiden's coy reply is contained in "*Hvadfor ikke det?*"—"Why not?" Our last and best memory of Orstenvik was gleaned at the quay. The school children, boys and girls, were gathered there to see the strangers off, and, led by a fair-haired maiden, with soft shy eyes like a fawn's, they sang us snatches of their national songs in the hush of the golden afternoon. Pure and clear as chiming bells the voices rose and fell in strangely sweet cadence, with never a harsh note to mar their perfect harmony. It was like the soft sighing of the wind amongst the pines, like the melody of the mountain streams, musical and silver-clear, but with ever an undertone of sadness. They sang their National Anthem, set to the same tune as "God save the Queen," and with that we parted, their voices still seeming to linger in the soft warm air. From Orstenvik our course lay westwards through the islands out into the open sea, and down the coast till we came to the great Sogne Fjord. It was midnight by the time we entered the fjord, though only our watches could make us believe it. On the way great excitement was caused by the rising of the moon, large and lurid, above the horizon in the far east. Captain Bentzon, being appealed to, mischievously gave his authority to the hesitating statement that it was the midnight sun, and great was the number of those that were hoaxed. But there was no mistake about the rainbow that spanned the heavens just before the sun set. Out of the sea it rose and into the sea it fell; and where it rose and fell the waves were flooded with the brilliant colours of the soaring pillars, glowing with unusual brilliancy in that clear air.

(To be continued.)

## Gelatino-Chloride of Silver Printing for Paper and Opals.\*

By H. WADE.

THE process of printing out on opals is not a new one—rather the opposite—as will be seen by looking at some of the old journals, etc.; but the photographer of the present time appears to have forgotten its existence altogether, and employs the bromide opals instead. In addition to the monotonous uniform black tone presented by bromide opals, they seem to have a dead sunken-in appearance.

And now look at the cost, the lowest price of half-plate bromide opals is 5s. 6d. per dozen, while 3 oz. of chloride emulsion is 5d., sufficient to coat one dozen opals; plain opal glass, half-plate size, costs about 2s. per dozen.

The ease of acquiring any tone ranging from red to a bluish-black offered by the gelatino-chloride process, is also another consideration. As to permanency, if the plates are well fixed and washed, I see no reason why they should not be equal with the bromide.

The following is the formulæ which I have found best for the emulsion; being simple in its constituents and easy to manipulate. For the solutions take:—

	No. 1.
Silver nitrate .. .. .	$\frac{1}{4}$ oz.
Citric acid .. .. .	1 drm.
Water .. .. .	1 oz.
	No. 2.
Gelatine .. .. .	$\frac{3}{4}$ oz.
Water .. .. .	6 oz.
	No. 3.
Alum .. .. .	20 gr.
Rochelle salts .. .. .	20 gr.
Ammonium chloride .. .. .	10 gr.
Water .. .. .	1 oz.

Dissolve Nos. 1, 2, and 3 in separate vessels, then mix Nos. 2 and 3 together, and gradually add the silver solution to the salted gelatine, very slowly stirring during the whole time, so as to obtain a fine chloride of silver. If it is added in a mass the particles are apt to be coarse. When well mixed, heat up to 150 degrees, and filter through two thicknesses of muslin. (With this emulsion, washing is dispensed with.)

Other formulæ may be used, but for simplicity and beauty of results, I prefer the one just given.

See appendix A for citro silver emulsion.

Before proceeding with opals I will describe a method of coating paper suitable for printing out.

The paper should first have a coating or sizing made by dissolving  $\frac{1}{4}$  oz. of gelatine in 10 oz. of water and adding 5 gr. of chrome alum.

Porous or soft paper should be immersed in this solution, but if a hard make of paper is used it should only be coated on the smoothest side. If a very smooth surface is desired, it is better to apply a second coat after the first has been allowed to dry.

When hanging the sheet, take up the opposite corners of the paper to those previously laid hold of for the first coating, in order to have it even. When dry, roll around a ruler or something similar, the side to be covered with emulsion being outwards. This coating of gelatine is perfectly insoluble in hot water.

The final support employed for single transfer in the carbon process, may be used by those who wish to avoid the risk of not obtaining an even surface. The paper is suitable and the coating is very even and quite insoluble.

The following remarks on coating the paper with the emulsion will apply to coating the paper on *one side* with the gelatine.

Pour the emulsion into a shallow porcelain dish, which for preference should be standing in a larger dish filled with hot water, so that the emulsion may be kept from congealing too rapidly.

Take the paper to be coated by the two opposite ends, and place it on the emulsion. Let it stop a few seconds, then lift up one corner, and afterwards the other, to see if there are any air bubbles. Should these be observed, touch them with a glass rod

The Monday afternoon "At Home" is discontinued for the present, but will be resumed on Monday, the 5th of September.

\* Read before the Manchester Camera Club.

or match stalk, to burst them. When the paper lies quite flat, take two uprights (a book or anything of the right size and shape will do) and place them at each side of the dish, about one inch higher than it. Then place a piece of glass, larger than the paper to be coated, on the uprights, and over the dish, but about two inches from one end. Lift the paper up by two corners, and draw it slowly over the glass and on to it. Leave for a few seconds to set, then hang it up in a warm dark place, free from dust, to dry.

After the coating, the operations of toning, etc., are identically the same as opals, which I will now describe.

The opals to be coated should first be examined to see that they are perfectly even. If not, they must be ground with emery until the surface is uniform. They should also be quite free from grease or dirt. Soaking from half-an-hour to one hour in a weak solution of hydrochloric acid and water, and finishing with a clean rag, will effectually cleanse them.

Coating opals is a "knack" which needs to be acquired by practice; but the easiest way, I consider, to deal with ground opals is to pour the emulsion in a pool in the centre of the plate, then guide it with a glass rod or the middle finger (mind it is perfectly clean) to the edges. Pour off the superfluous emulsion into a jug, leaving only a thin film on the plate.

Place the opal on a level surface to set.

Smooth, or flashed opals are much easier to coat than those with a ground surface, and the emulsion runs to the corners without any guiding.

When set, place the opals on a rack and leave them in a dark place to dry.

If placed in an ordinary room, after they have been prepared in the evening, they will be ready the following morning for printing.

All operations, including the preparation of the emulsion and coating, should be performed by gaslight or weak daylight.

Instead of a jug, a small tea-pot may be used advantageously in coating the opals. The spout coming from below the surface prevents air bubbles from being poured over the plate.

One of the advantages of making your own emulsion is that you can alter it to suit your negatives. The one given is a medium emulsion, suitable for negatives of ordinary density—it may be termed a rather thin quality.

If we wanted to print from a *very* thin negative, we should make up an emulsion with fifteen instead of ten grains of ammonium chloride; and for hard negatives *vice versa*.

If the opals, when prepared, are kept wrapped up in oiled paper, they will keep for two or three weeks, but they are better used fresh.

It is rather difficult to examine them during printing, as we cannot turn them back like paper; but it becomes easy enough after a little practice, either by taking the opal away from the negative completely, and if not sufficiently printed, to superimpose it carefully on the negative again until the image is fully printed; or by looking at the opal through the negative while in the frame, towards a strong light. Another method is to coat a piece of paper with the emulsion and, selecting a negative of the same density as the one to be printed, place the paper behind it. By placing both opal and paper out to print side by side you will be able to see by the paper being complete that the opal is also dark enough.

The printing of both should be continued until they are a little deeper than would be required for an albumenised print.

After printing, wash until all free silver is removed; about four changes of water.

The opals and prints I have brought with me have all been toned in the toning-bath recommended by the Ilford Company for use with their chloride paper. An acetate bath may be used—appendix B. To obtain a purple tone, withdraw the opals from the bath while there is a shade of brown in them. They dry with a much colder tone than they present while wet.

Immediately the required stage has been reached, place them in a 20 per cent. solution of salt and water, and after a rinse, fix in a 10 per cent. of hypo for ten minutes.

If a hard make of gelatine is used (such as Hienrech's), an alum bath is not required; alum being one of the constituents of the emulsion.

The washing need not be continued so long as for albumenised prints one hour for the opals and two hours for the paper, in running water, is sufficient.

The process, while taking rather long to describe, is a simple one, and I think that if any try it they will be agreeably surprised at the results.

## APPENDIX.

### A.—CITRO-SILVER.

#### No. 1.

Silver Nitrate	..	..	..	..	75 gr.
Water	..	..	..	..	1½ oz.

#### No. 2.

Gelatine	..	..	..	..	80 gr.
Water	..	..	..	..	½ oz.

#### No. 3.

Sodium or Ammonium Chloride	..	..	..	21 gr.
Potassium Citrate	..	..	..	21 gr.
Water	..	..	..	½ oz.

When all are mixed add

Alcohol	..	..	..	2 drm.
Citric Acid	..	..	..	3 gr.
Chrome Alum	..	..	..	1 gr.

### B.—ACETATE BATH.

#### Stock.

Acetate of Soda	..	..	..	2 drm.
Bi-Carbonate of Soda	..	..	..	20 gr.
Gold	..	..	..	1 tube
Water	..	..	..	5 oz.

#### Bath.

Water	..	..	..	20 oz.
Stock	..	..	..	½ oz.

For about every 80 prints toned, add 1 to 2 drams of stock.

## Reviews.

*Fortschritte in der Photographie* by J. M. Eder and E. Valenta. An abstract from the *Jahrbuch der Chemie*. Published by H. Bechhold, Frankfurt a/M.

This is a brief retrospect of the advance of photography during 1891, compiled by Eder and Valenta, for Meyer's *Jahrbuch der Chemie*. In the eighteen pages the compilers have done their work well though briefly, and if the remainder of the Yearbook is up to this standard it will be worth reading.

*Bromide Enlarging and Contact Printing: How to do it.* By A. R. Dresser. Published by the Fry Manufacturing Co, Chandos Street, Charing Cross, W. Price 6d.

The author gives us brief but practical directions for using bromide paper, and unencumbered as the book is with unnecessary matter it will be of considerable service to beginners in this branch of work. Where required diagrams are inserted to make clear directions clearer still.

*Photographic Enlargements: How to Make Them.* By George Wheeler. Published by Wheeler and Co., 46, King Street West, Manchester. Price 1s.

Mr. George Wheeler has given us in this little brochure of 130 pages, a practical common-sense handbook to enlargement-making. Every statement bears the hall-mark of experience, and everything is told in a plain straightforward manner, which is extremely easy of comprehension. After a brief preliminary note as to why enlargements should be made, we have the usual table of distances, then a section devoted to the paper, and methods of keeping it; we then come to the negative, and this is carefully considered; then the pros and cons of daylight and artificial light. Enlarging by daylight and the necessary apparatus; and how to make the same is then considered, and clear diagrams are introduced. Artificial light receives due notice, and we then come to the actual working operations of exposure, printing in skies, vignetting, developing, clearing, fixing, washing, etc., and then the final hints on spotting and retouching, and defects and their considerations. The work is well printed and well written, and deserves recognition from all who desire to make enlargements.

## The Theory of Development.\*

IN RELATION TO THE ESSENTIALLY ELECTROLYTIC CHARACTER OF THE PHENOMENA AND THE NATURE OF THE PHOTOGRAPHIC IMAGE.

By MR. HENRY E. ARMSTRONG, F.R.S.

*Professor of Chemistry in the City and Guilds of London Central Institution.*

No pretension to be even a professional amateur photographer is made by the writer of these lines. At intervals extending over a considerable period he has exposed and developed plates in a conventional and rule-of-thumb manner, but about a couple of years ago an awakening of his photographic conscience took place, and he began to ask himself whether he had any true understanding of what he was doing? Finding that he had not, and that the text books afforded but cold comfort, he bethought him that he was working in a manner utterly unworthy of a member of that fraternity which seeks to give its meaning to the watchword by which it is led—Science: "Knowledge co-ordinated, systematised, and arranged."

To-night he will attempt but a very general confession of the faith that is beginning to arise within him after much pondering over photographic literature, and after a couple of years of study and experience of the behaviour on development of plates exposed in the field at all seasons, and under a considerable variety of conditions, one chief object in view having been to arrive at the explanation of the controlling influence exercised by the restrainer, and the accelerating effect of alkali.

Thus much by way of perface. A prologue may be added to facilitate the explanation of points of fundamental importance.

In the year 1868 De la Rue and Muller described a new form of voltaic cell, consisting of a cylinder of silver chloride cast around a silver wire as negative element opposed to a zinc rod as positive element, placed side by side in a tube containing a solution of a chloride—ammonium chloride, being that ultimately preferred. [It is worth while noting that they speak of silver chloride as so poor a conductor of electricity that it may be regarded as an insulator, and that on this account it is necessary that the silver wire around which the chloride is cast should project through it into the solution. On the other hand, it is also noteworthy that even solid silver chloride may be electrolyzed, and that directly its temperature is raised sufficiently to make it viscous, it is an exceedingly good conductor.] In such a cell the silver chloride remains unchanged until the circuit is completed by joining the zinc and the silver by a conductor of electricity; immediately this is done a current passes, and simultaneously zinc dissolves and silver chloride becomes deprived of chlorine. Although ammonium chloride is used in the cell, in considering the nature of the interchanges, it is permissible to assume that hydrogen chloride—one of the constituents of ammonium chloride—is the active agent; for, as will be shown later on, at the same time that hydrogen chloride is being withdrawn from ammonium chloride and used up, hydrogen chloride is being produced and converted into ammonium chloride, and as the two actions balance each other, it is unnecessary to consider them.

Supposing that silver, and not silver coated with silver chloride, were opposed to the zinc in the cell, the latter would dissolve as chloride; but hydrogen would be given off at the surface of the silver. In this case the current would rapidly fall off, the cell would become *polarised*, in consequence of back action setting in between the hydrogen coating the silver and the zinc chloride, which would lose chloride. As it is reversible, the change occurring under such conditions may be written—

i.e., the equation may be read either backwards or forwards. In the presence of silver chloride in contact with the silver, this back action or polarisation is prevented, no hydrogen ever being set free, as at the same time that the zinc combines with chlorine from the solution an equivalent amount of hydrogen combines with chlorine of the silver chloride, and thus the amount of chlorine, as ammonium chloride in solution, is maintained constant. We, therefore, may represent the state of affairs in the cell before and after the current passes in the following manner:

Zinc plate	Cell at Rest.	Cell in Action.
	$\begin{array}{ c c } \hline \text{ClH} & \text{ClAg} \\ \hline \text{ClH} & \text{ClAg} \\ \hline \end{array}$	$\begin{array}{ c c } \hline \text{HCl} & \text{Ag} \\ \hline \text{HCl} & \text{Ag} \\ \hline \end{array}$
= Zinc plate	Zn	Ag { silver plate

The electrical pressure developed in such a cell—its electromotive force, or E.M.F.—is about 1.05 volt; the theoretical value may be calculated in the following manner:—

It is known from thermo-chemical measurements that the dissolution in dilute muriatic acid ( $\text{HCl} : \text{H}_2 \text{ O} = 1 : 200$ ) of sufficient zinc to displace 2 grams of hydrogen would involve the evolution of 34,200 gram-deg. C.-units of heat.

If this amount of hydrogen and the equivalent amount of chlorine were to interact, and form hydrogen-chloride, 78,640 units of heat would be liberated; while by the interaction of the equivalent amounts of silver (216 grams) and chlorine only 58,760 units of heat would be liberated. Consequently  $78,640 - 58,760 = 19,880$  units of heat would be developed if the hydrogen, instead of being liberated, were to reduce silver chloride, and the total heat evolution resulting from the conversion of the zinc into chloride at the expense of the chlorine withdrawn from the silver chloride would be  $19,880 + 34,200 = 54,080$  units. The corresponding E.M.F. is found by dividing by 46,000, a constant which need not be explained here; hence—

$$\frac{54,080}{46,000} = 1.18 \text{ volt.}$$

The difference between this and the observed value is attributable to the fact that the conditions for which the calculation is made are not precisely those which obtain in an actual cell; probably the zinc chloride is not fully hydrated in the electrical circuit, and the heat of formation of some less hydrated chloride should be taken for the purpose of the calculation.

The extent to which electrolysis of silver and hydrogen chlorides takes place, i.e., the amount of zinc dissolving and of silver chloride reduced in the cell depends on the resistance in the electrical circuit, since—

$$C = \frac{E}{R}$$

where C stands for current, E for electromotive force, and R for resistance. This [is the well-known *Ohm's Law*: its importance in connection with photographic phenomena has been strangely overlooked.

To apply this law to chemical changes, it has merely to be borne in mind that C may also be taken as meaning amount of chemical change, and it is scarcely necessary to point out that the most exact method of measuring an electrical current consists in determining the amount of chemical change which the current produces by weighing the deposit of silver obtained on passing it through a silver nitrate solution. E, as before, is the electromotive force corresponding to the interchange, and R the resistance, not of the liquid as a whole, however, but of the circuit within which the interchange is effected, which may be quite a different thing, and unfortunately at present is beyond measurement.

It will be noted that the E.M.F. of the silver chloride cell is the sum of two E.M.F.'s, the one developed in the formation of zinc chloride from zinc and hydrogen chloride, the other in the reduction of silver chloride. In any case, in order that action may occur, it is essential that the change, on the whole, be one in which energy is set free; but this is not necessarily the case in all parts of the change when it is resolvable into parts. This is a consideration of primary importance in connection with the theory of development, and may be illustrated by the following examples:—Zinc readily dissolves in diluted sulphuric acid if coupled with a less positive conductor. Copper, however, does not, even if the acid be boiled; but copper dissolves readily enough if oxygen be passed into the heated diluted acid. Thermo-chemical measurement shows that while the dissolution of sufficient zinc to displace 2 grams of hydrogen from sulphuric acid is attended with a liberation of energy expressed by the number 37,730 if represented in heat units, the dissolution of the equivalent amount of copper could only take place if energy were supplied to the extent of 12,400 heat units; but, as oxygen and hydrogen interact, forming water, with liberation of energy to the extent, measured in heat units, of no less than

## OUR VIEWS.

"To hold as 'twere the mirror up to nature."—*Shakespeare.*

The Monday Afternoon "At Home" is discontinued for the present, but will be resumed on Monday, the 5th of September.

OUR VIEWS.—"Sun Pictures"—Photography at Home Competition Awards—American Journalism—The Convention—The late Mr. C. V. Shadbolt.

LETTERS TO THE EDITOR.—The Blister Fiend (P.)—Correct Tones (Darroch).

REVIEWS.—The Photographer's Companion (Dunmore)—*Photography Annual* (Iliffe).

APPARATUS.—Watkins' Exposure Meter—Everybody's Hand-Camera.

ARTICLES.—Elementary Photography (Hodges)—The Lantern, and How to Use It (Norton)—A Holiday in Norway.

SOCIETIES' MEETINGS.—Eastbourne—Hackney—Harlesden—Kensington and Bayswater—Leytonstone—Lewes—North London—North Middlesex—Sheffield—South Manchester—South London—Southsea—Tunbridge Wells.

EDITORIAL DEPARTMENT.—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

### TERMS OF SUBSCRIPTION—

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	" " 6s. 6d.....	" " 12s. 0d.
OUT OF POSTAL UNION ..	" " 7s. 9d.....	" " 15s. 8d.

TRADE ADVERTISEMENTS are received up to Tuesday morning.

PUBLISHING DEPARTMENT.—All letters containing Subscriptions, Orders, Remittances, SALE and EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZELL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition, No. 38.—"INLAND SCENERY WITH OR WITHOUT FIGURES." Latest day, July 25th.—Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, August 19th.)

It has always been our custom to issue annually a Special Number containing the choicest pictures sent in to our "Holidays with the Camera Competition." Hitherto these special numbers have been illustrated by means of half-tone or process blocks. Our publishers are now ready, as they announce on another page, to supply copies of the Special Number of the 1891 "Holidays with the Camera" competition, which has been issued under the title of "Sun Pictures from many Lands," and we venture to think this is the most artistic of any Special Number which has yet appeared from our office.

"Sun Pictures" contains two frontispieces, "Near Upminster," by Francis Powell; and "St. Gillingham," by S. Francis Clarke, both being finely reproduced in Woodbury-gravure. In the seventy-nine pages of letterpress, comprising the accounts of the competitors' tours are included no less than thirty-six collotypes, viz. :—

"Children Crossing the Allan;" "The Allan Water;" "The River Leith, Callander." By FRANCIS POWELL.  
 "On the Lynn;" "Salisbury Cathedral from the River Avon." By Rev. T. PERKINS, M.A.  
 "H.M.S. Ruby;" "Portsmouth Harbour." By J. E. J. and M. ELLIS.  
 "Ben Lomond, from Rowardennan;" "Skiddaw, from Bassan-thwaite Lake." By W. LAMOND HOWIE.  
 "Constantine—The Arab Market;" "Biskra—A Caravanseraï." By CYRIL S. COBB.  
 "Lotefos;" "Stalheim." By R. H. LLEWELLIN ROBERTS.  
 "Elephant Convoy;" "A Batch of Chins." By Surgeon A. G. E. NEWLAND.  
 "Dean Odo's Doorway;" "Great Cross, Clonmacnoise." By D. GOODWILLIE.  
 "The New Albertina—Coming In;" "A Storm." By A. R. DRESSER.  
 "Criccieth Castle from Blackrock." By J. OSWELL BURY.  
 "Andermatt;" "At Bellagio, Lake Como." By E. W. BASSANO.  
 "Derwentwater;" "Derwentwater." By C. W. DAVIES.  
 "Beaver Pool, Bettws-y-Coed;" "A Peaceful Spot." By HARRY HOLT.  
 "A North Hincley Cottage;" "Divinity School, Oxford." By C. COURT COLE.  
 "Cortina;" "Street in Sterzing." By ALFRED STIEGLITZ.  
 "An Autumn Morn;" "Ready for School." By JOHN H. GEAR.  
 "The Greek Theatre, Taormina;" "The Theatre of Herodous Atticus, Athens." By RINGROSE ATKINS.  
 "Framwellgate Bridge;" "The Crypt." By H. Meynell.

Each illustration is in itself a picture. They are, in fact, the pick of the prints sent in to the competition, and being reproduced in collotype, though small, they form a most valuable guide, not only in composition but also in light and shade, as to the style and class of work required for such competitions.

Another feature, and one of which we think we may

justly be proud, is that this is the first time that this method of illustration, the interspersing of collotypes with letter-press, has ever been attempted in England.

The edition is limited, and therefore we strongly advise all our readers who wish to secure a copy of this so far unique publication, to secure the same at once, as a second edition cannot be issued. The work forms an exceedingly handsome *edition de luxe*, which will form a really artistic addition to any worker's library.

MESSES. H. P. ROBINSON AND VALENTINE BLANCHARD have during the past week adjudicated upon the prints sent in to our "Photography at Home" Competition, with the following result:—

Gold Medal. . MRS. S. FRANCIS CLARKE, Louth.

" " CLARENCE B. MOORE, Philadelphia, U.S.A.

The judges, wisely, we think, refrained from discriminating between these two sets. Mrs. Clarke's pictures are certainly some of the finest figure slides (platinotype) we have ever seen, and we heartily congratulate her upon having won one of the premier prizes in this competition, and although it is well known that she is one of our foremost workers in this department no one will begrudge her this Gold Medal, a companion to that won in the Ladies' Competition. Mr. Clarence B. Moore's pictures are also platinotypes; two especially calling for especial mention from the judges.

Silver Medal .. A. J. LEESON.

" " .. ALFRED STIEGLITZ, New York.

The most striking picture in Mr. Leeson's exhibits is a perfect example of combination printing, and we unhesitatingly say that no finer example of this by no means easy process has ever been seen. Mr. Stieglitz's prints show extreme care both in selection and technique.

Bronze Medal .. FRANCIS POWELL, Dunoon.

" " .. EDGAR G. LEE.

Four of Mr. Powell's prints are made to tell a tale, "The Days when we were Young," and we need not say that, like all the work from this competitor, are extremely careful and very artistic. Mr. Edgar G. Lee wins with some charming hand-camera studies, which might have been made more of in the printing.

Certificate .. J. P. GIBSON, JUN., Hexham.

" .. A. L. SPILLER, Hampstead.

Mr. Gibson, jun., is well known to us for a very careful young worker, and his little quarter-plate prints have all been carefully thought out and carried out. Mr. Spiller was exceedingly happy in one sitter, who figures more than once in his prints.

We intend to issue a Special Number, embodying a selection, if not all the prize pictures, and we hope to be able to produce them of large size, and thus make a second number, and worthy companion to "Sun Pictures."

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

The peculiar style of journalism so prevalent in America is evidently gradually gaining ground here. The following appears in one of our contemporaries of last week:—

"One of the most curious things which has appeared in the photographic press for some time was 'A. R.'s' advertisement of his Kodak in our Emporium last week. 'A. R.' started button pressing without any previous knowledge of photography, and expected to get pictures every time. His frank avowal of failure and explanations of the reasons why are refreshing nowadays, when men hide their failures and pose as know-alls, and will form a good object-lesson to hand-camera beginners—for they are as applicable to any hand-camera as to the Kodak—and help to show such that the hand-camera is not a sort of infernal machine with which, by turning the handle, they can do the photographically impossible. Judging by the cart-loads of letters which our Emporium department have been forwarding to 'A. R.' since the advertisement appeared, it is plain that his frank avowal of incompetence has not frightened intending users of the Kodak, for the rush after that No. 4 has been just immense."

We have received the following information from the advertiser "A. R.," referred to in the above extract:—

"In answer to my advertisement, signed 'A. R.,' I received only three letters, one offering me a toy boat, the second offering me some lantern-slides in exchange, and the third another camera. This is absolutely all the response I got for my long advertisement."

The italics in both extracts are ours. *Verbum sap.*

WE have received a letter from Mr. S. Graves, of Littleborough, defending himself from the statement in our issue of last week. Whilst we regret if we have done him an injustice, we shall be glad to hear from any of our readers who have had dealings with him, and the matter is now being diligently enquired into, and we hope to report next week.

THE Photographic Convention was opened in the Hall of the Royal Scottish Geographical Society, Edinburgh, on Monday, at 6 p.m., by the President, Mr. Geo. Davison. The full text of the President's address and report of the meeting will appear in our next.

It is with great regret that we have to record the decease, on Friday last, of Mr. Cecil V. Shadbolt, from injuries received at the unfortunate balloon accident at the Crystal Palace.

## Letters to the Editor.

### THE BLISTER FIEND.

SIR,—Just a few more remarks upon a subject which has very nearly been thrashed out. I am glad to notice another person has tried "John Browning's" recipe with success, but it is acknowledged by that person that the spirit was used after toning, instead of before washing out the silver nitrate, which makes a vast difference. If the spirit can be employed after toning with the same result as "John Browning" claims for it, it may possibly be a safe remedy. Your correspondent, "John Browning," by the two questions in his letter, suggests that possibly my failure was due to not strictly following his advice, and I answer, I am not quite such a flat, anyhow in following advice for the safety of a thing which, if ruined, means loss of money, as the state of my prints mentioned in my last letter might cause your correspondent to think I am. I am not prepared to say whether the spirit I used was pure or not, but I made the stipulation, when buying it, that it was to be the best. I washed the prints in an ordinary circular washer, with the water full on, for a considerable time. I felt convinced I had taken the prints out of the water too soon before toning, from the greasy feeling of their surface, but the amount of washing I gave them did not in the least degree eliminate the grease, so I thought I would risk ruining them by placing them in the toning

bath. Considering my procedure before fixing, I did nothing short of following your correspondent's advice. However, I will try again, working in the way suggested by "H. S. Large," and also by "John Browning's" method, using fresh spirit, and the best that I can procure. With apologies for trespassing upon so much of your space.—Yours, etc., P.

\* \* \* \*

### CORRECT TONES.

SIR,—Being an amateur photographer, and having devoted nearly all my time to taking portraits, I have been much puzzled by the incapability of ordinary dry plates to reproduce contrasts in colour with any accuracy. I know that this difficulty is in a great measure avoided by the use of Isochromatic plates, but these are troublesome for a beginner to work. My failures are most often in the choice of a suitable background, as I generally select one either so light as to almost match the face, or so dark that the hair fades into it. It seems to me that by the use of a red glass this difficulty would be almost if not entirely obviated, for by looking through a red glass one sees yellow and red becoming virtually the same colour, and both fading away into black. Of course, any piece of glass would do; what I use is a pair of cheap pince-nez, with plain lenses, coated with Thomas's Liquid Ruby.

I am aware that an idea very similar to mine was suggested by Mr. Valentine Blanchard in the "British Journal of Photography Almanac" for 1892, but the blue glass proposed by him only reduces everything to monotint, whilst I think that my red pince-nez give me the relative values of the colours more as they actually appear in the resulting photograph.

To those who are far advanced in our art, no such aid is necessary, but for a beginner I believe my plan is of some practical use.—Yours truly, C. E. DARROCH.

### Reviews.

*The Photographer's Companion.* Being a Collection of Hints, Expedients, and Formulæ. By Edward Dunmore. Published by H. Greenwood and Co., 2, York Street, Covent Garden, W.C. Price 1s.

The author in his introductory remarks states his idea was not "to make it a complete book of instructions, or a history of the progress and practice of the art, but rather a supplementary reference book," and it certainly will be found exceedingly useful in this respect. Mr. Dunmore is well known as an experienced craftsman, and what he has to say bears the imprint of practice. The arrangement of the work is somewhat on the lines of the advances made in photography. First we have instructions for cleaning and copying daguerreotypes, then the wet collodion process, its suitability for photo-mechanical work, etc., then the collodio-bromide process. For the clear instructions on these processes alone, the work is worth having, and the succeeding portions treating of the now universal dry plates, copying, portraiture, printing, etc., add to the value of the work as a handy reference book.

*Photography Annual.* Published by Iliffe and Son, 3, St. Bride Street, E.C. Price 2s. 6d. in paper, or 3s. 6d. in cloth.

This annual is bulkier, if possible, than last year, and now forms a rather unwieldy volume. The contents are very much on the lines of the previous issue. Mr. Bothamley contributes a summary of photographic chemistry, Mr. Albert Taylor one on astronomical photography, Mr. Whipple on meteorology, Chapman Jones on optics, and Mr. T. Bolas on photo-mechanical printing. Besides these summaries are articles by various writers, and a very large section devoted to apparatus, compiled by W. D. Welford. The work is illustrated with several collotypes and process blocks, and is well printed and got up.

### Apparatus.

#### WATKINS' EXPOSURE METER.

THIS little instrument has become part and parcel of many an amateur's outfit, and Messrs. R. Field and Co., of 142, Suffolk Street, Birmingham, have sent us one of the same fitted with the extra enlarging ring.

The instrument is almost too well known to need any description, but it is a brass tube with revolving rings which are

marked with various letters, P, S, D, A. At one end of the tube a cap, which is removed and will then be found to hang by a chain which allows the same to swing, forming a pendulum beating half seconds. At the other end is a small, light-tight case with a standard tint covered by glass and a roll of specially sensitised paper. The cap is removed and set swinging, and the sensitive paper exposed "to face the source of the light which falls upon the subject, not to face the subject." This is a point where many fail; the paper is either exposed towards the subject or else carelessly in the operator's own shadow, not in the full light. If there is a heavy shadow in which detail is required, then the paper should be exposed in shadow, but where there is an insignificant shadow this may be neglected. The number of seconds taken for the paper to darken to the standard tint is the actinometer or A number. In testing the light the depth of tint is the important point. The paper darkens rapidly in light; up to a certain point it is lighter than the standard tint, after this point it is darker! The point when it is neither lighter nor darker is that to be timed. There has always been some question about this, and the best plan we have found is to hold the actinometer about two feet from the eye, when the tint is readily matched, at this distance the precise point when the paper matches the tint being readily determined. Having found out the A number, the ring marked P is set to the number corresponding to the speed of the plates, and in the little book of instructions issued by the makers is a table of P numbers which have been actually determined by Mr. Alfred Watkins from camera tests. The next pointer marked S is set to the subject number, the only case where individual judgment comes in using this meter; then the D or diaphragm pointer is set to the proper stop aperture, and the A or actinometer number is then fixed, when the outside pointer E marks the correct exposure.

This instrument may be used for determining the speed at which to work shutters, or what stop to use with a given speed of shutter, for copying, enlarging, and lantern slide making, for which purpose a special form of instrument with an extra ring is provided, and also for contact printing by daylight and classifying negatives.

We have had one of these meters in use for some time, indeed it accompanied us on our Easter trip, and we have given it a very severe trial on all sorts of subjects and in all kinds of lights, and have found it a very valuable and reliable guide to that always difficult subject, a correct exposure.

#### A NOVELTY IN COLOURS.

Mr. Conrad Schulz, of Room 29, 82, Bishopsgate Street, E.C., has submitted to us some samples of photographs on silk, most artistically coloured. The process is extremely simple, and the materials by no means costly, and may be used by any worker, even those ignorant of the art of painting or colouring. The results obtained are so artistic and natural that we prophesy a very hearty support for this novelty, which has been very well received on the Continent.

### Catalogues.

WM. HUME, 1, Lothian Street, Edinburgh. Illustrated Price List of Photographic Apparatus.

A well compiled and illustrated pamphlet of all photographic and lantern requisites, an especial feature being, of course, Mr Hume's well-known Cantilever enlarging apparatus.

ARCHER AND SONS, 43 to 49, Lord Street, Liverpool.

A well arranged price list of 70 odd pages, containing all the photographic specialties made by this firm or for which they are agents. One of the salient features are the sets this firm are now offering, and which strike us as being well worth attention. The "Liver" camera too is another high-class novelty they are introducing. A special and separate catalogue is devoted to lanterns and lantern appliances, one branch of the business Messrs. Archer have deservedly won their name in.

A PHOTOGRAPH, AND HOW TO TAKE IT. By "One who Knows." Published by E. G. Wood, 74, Cheapside, E.C.

This is rather more than a mere price list, as nearly half the book is taken up by concise and clear explanations of its title. We need hardly add that the price list forms a very useful adjunct to this literary part.

## Elementary Photography.

By JOHN A. HODGES.

### CHAPTER XXIV.

#### SOME ELEMENTARY OBSERVATIONS UPON THE ARTISTIC TREATMENT OF THE SUBJECT.

The Aim of the Writer—The Advantages of an Artistic Training—The Necessity for Study—Books to be Read—Some Leading Ideas—The Principal Object—Adjustment of Focus—How to Proceed—The Proper Use of Stops—Groups and Figure Subjects—The Pyramid—The Position of the Principal Object—Photographing Streets—Repetition of Lines—Balance—Light and Shade—The Shortcomings of Photography—Choice of Subject—Simplicity—Subjects to Avoid—Motive—The Position of the Horizon.

ANYTHING in the nature of a treatise upon art would obviously be out of place in an elementary text-book, but photography and art are so closely united that to entirely abstain from referring to the subject would certainly be wrong.

I would say, at the outset, that the reader who takes up photography, possessing some prior knowledge, however slight, of composition, balance, light and shade, will find even a superficial knowledge of art principles of the greatest possible assistance in attempting to secure pictures by photographic agency.

It may, unfortunately, be said with truth of the majority of photographers that they care little for, and pay small heed to, artistic considerations in the pursuit of their hobby. A great many people, having mastered all technical details, go on year after year producing photographs good from a technical point of view, but entirely lacking in pictorial merit. This, however, would not be the case if some slight attention were paid to the elementary principles which govern composition. It is, of course, infinitely easier to acquire a knowledge of photography than to learn to be an artist, but there is no reason why a small amount of study and training should not make the reader a little of each.

It must not, however, be inferred from the foregoing observations that the mere knowledge of certain so-called "rules of art" will enable the reader to straightway go and produce good pictures. The two best books upon this subject, *which a photographer can refer to*, have been written by Mr. H. P. Robinson, and are called "Picture-Making," and "Pictorial Effect in Photography." I would strongly advise the reader to obtain copies of these, and "read, mark, learn, and inwardly digest" their contents.

Photographic views which are of an essentially topographical character may very often, by a little careful attention to the selection of the point of view, be considerably improved, but with such subjects I am not for the moment dealing.

It should always be remembered that every successful picture possesses some leading idea, some principal object of interest, all the rest being merely accessory or subordinate. The photographer, therefore, should always endeavour to give emphasis to the principal object by focussing it carefully and making it the sharpest portion of his picture, and by careful adjustment of the focus it is possible to gain an effect of atmosphere and distance. In order to produce this effect the largest stops permissible should be used. As I have said, the principal object should be focussed sharply with the open aperture of the lens. If this object be in the immediate foreground, as it generally will be, the middle distance and distance will possibly be very indistinct and fuzzy; smaller stops should then be inserted until the middle distance is fairly but not microscopically sharp, the distance may then be left to itself. *F/16* is a most useful aperture,

and, if possible, a smaller stop should not be used, except it be for architectural subjects or special purposes.

In taking a group, or in composing a picture in which several figures form a prominent part, anything approaching symmetry, like a file of soldiers standing at "attention" (fig. 1), should be studiously avoided, and the figures grouped in a pyramidal form, as in fig. 2.

One of the rules of art to which I have referred is that the lines of the composition should be so arranged as to form a pyramid or series of pyramids. A striking example of this is to be found in Wilkie's "Blind Fiddler."

The principal object should never occupy a central position in the picture, for the centre in reality is its weakest point. For instance, in photographing a landscape with buildings, the latter should not be in the centre, but rather to the right or to the left; figs. 3 and 4 are illustrations of this. In the same way in photographing a street scene, the camera should never be placed in the middle of the road, but on one side, either to the right or left, so that the vanishing point may not occur in the centre of the picture. Try and avoid a repetition of lines as in fig. 5, either perpendicular or horizontal, because monotony is introduced, sloping lines opposed to each other are far more pleasing (fig. 6). By following this rule the effect known as "balance" will be obtained, and the picture rendered in a pleasing and effective manner.

Now, a few words on a most important subject, and one over which the photographer has some slight control; I refer to "light and shade." In dealing with form, the photographer is somewhat heavily handicapped, but, by making the exposure at the right time of day, and when the subject is most suitably lighted, he will be able to secure just the effect of light and shade desired. One reason why such a large number of photographs are so unpleasing, although the composition may be good, is due to the spotty and scattered nature of the lighting. This is particularly noticeable in landscape subjects where there is much foliage. The light is reflected from the small leaves in a distracting manner, which detracts greatly from the general effect. The light and shade in a photograph should be massed as much as possible, so as to secure breadth; very fine effects are sometimes obtained by bringing the highest light into strong contrast with the deepest shadow. But here it is necessary to remind the photographer that he cannot reproduce on a photographic plate the exact gradation of light and shade existing in nature, for, as I have endeavoured to explain in the chapter upon isochromatic photography, ordinary plates are less sensitive to some colours than to others, particularly to yellow and green, and it is for this reason that isochromatic plates are so markedly superior for landscape work. A great many landscapes excite our admiration solely on account of the beauty of their colouring, and this fact the photographer should always bear in mind. The plan is adopted by some, and it is one to be commended, of looking at the selected view through a piece of blue glass, or a pair of blue spectacles, it will then be seen whether the effect is due to local colouring only, or to a fine disposition of light and shade.

In regard to choice of subject a volume might be written, but here I must content myself with a few words. The beginner should confine himself to landscape pure and simple until he has made himself thoroughly acquainted with the use of his tools. Having done so he may then try the introduction of animals or figures into the composition, but only, of course, allowing them to occupy a subordinate or accessory part in the picture. Figure, *genre*, and group studies are to the photographer the most difficult of all, and the beginner, who has received no art training, would do

well not to attempt them until he has acquired considerable proficiency in dealing with simpler subjects.

Simplicity, both in the subject and its treatment, is really the key-note to successful picture-making with the camera and lens. Extensive landscapes, seen perhaps from well-known view points are seldom well rendered in a photograph. A little bit of leafy lane, with a thatched cottage peeping through the trees, will probably make a far more pleasing photograph than a mountain range, or a wide tract of country. Remember the limitations of photography, and beware of attempting too much. Let every picture have a motive, and, as it were, tell its own tale; avoid meaningless composition—a collection of accessories without aim or object. As an example of this, contrast fig. 7 with fig. 8, and note how easily an ordinary and even uninteresting scene may, by very simple treatment, be imbued with the picturesque.

I will conclude these brief comments upon what is really a very wide subject by a brief reference to a most important matter, viz., the position of the horizon line. It should rarely, if ever, be absolutely central, cutting the plate, as it were, into two equal portions. Whether it be high or low must, to some extent, depend upon the nature of the subject, and the effect sought for. When photographing in a flat country, if it be desired to give the impression of distance, the horizon should be kept low, and should not be higher than one-third up the plate. If much foreground be included in pictures of this class, the feeling of distance is to some extent lost, owing to the fact that the lens, as a rule, includes too wide an angle of view, giving undue prominence to near objects, and consequently dwarfing the distance. A low horizon is generally easier to manage than a high one, though there are occasions when the high horizon is very effective. This is often the case in marine work, and particularly with upright pictures, but it will generally be safe to place the horizon line about one-third from the base of the picture.

I have now, I trust, written sufficiently upon this topic to induce the reader to seek further knowledge from such books as those from the pen of Mr. Robinson to which I have already referred.

[Owing to delay in the preparation of the blocks, the illustrations which should accompany the text are unavoidably held over until the publication of "Elementary Photography" in book form.—ED : AM: PHOT: ]

**Absorption and the Photography of Colours.** By M. Labatut. (*Bull. Soc. Franc. Photo.* [2], 8, 58.) According to the author, when an ordinary sensitive plate is treated by the Lippmann process the impression is obtained very slowly, but if the plate be dyed with a colouring matter having well defined absorption lines, after developing and drying it will be found to show coloured bands. That the photographic impression is produced by the absorbed rays is shown by the fact that if a material dyed more strongly with the same colouring matter be held in the path of light, the photographic impression will not be produced. Hence the author says that if in Lippmann's experiment it be proposed to obtain an impression of given radiations, it will be sufficient to choose a sensitive plate coloured to absorb this radiation, and no coloured screen will be necessary. A Victoria green absorbs the red orange, and a plate dyed with this green and treated as in Lippmann's process showed this colour on its external face. In the same way cyanine absorbs the yellow orange and the green, and in a plate dyed with it these same radiations are seen. But when the plates are examined from the back the colours obtained appear to be complementary to those shown on the face. The author concludes that in consequence of the concordance between absorption and the photographic reduction, it is not necessary to use the spectroscope in order to obtain on plates the colours of thin layers. If a beam of white light falls on a coloured plate in contact with a mercury mirror there is interference. The absorbed radiations only impress themselves on the sensitised material and the others are transmitted without effect. The result of the impression is a colour which is the synthesis of those that would have been obtained by the use of the spectroscope.

## The Lantern, and how to Use it.

By C. GOODWIN NORTON.

(Continued from p. 8.)

### CHAPTER XIII.

WHEN preparing the lantern and apparatus for an exhibition, it is a good plan to make a list of everything that is likely to be required, and carefully check each article as it is packed, as the absence of one may seriously delay the exhibition, or even prevent altogether its being given.

Numberless mishaps have occurred from operators leaving something behind, or taking one article in place of another. The articles likely to be left behind and most inconvenient to dispense with are limes, gas-keys, regulator, carrier, reading-lamp, or jet.

With those hiring lantern apparatus care should be taken to see that the proper gas is supplied, and the regulator and keys fit, that the lenses are of suitable focus and have proper connectors to place them at the correct distance from the condenser.

Supposing nothing has been left behind, the first thing is to determine the position of the sheet, and fix it in such a position that the bottom will clear the people's heads, and also that the whole of the picture may be seen by the audience in comfort. If the room is very long and narrow, and long-focus lenses are available, it is a good plan to place the lantern at the side of the room against the wall; it will then be out of everybody's way; and to hang the screen obliquely, so that it will be at right angles to the centre of the rays of light. The screen may appear a little out of position to those sitting in front, but this is not noticeable after the gas in the hall has been lowered.

Most amateurs endeavour to show as large a picture as possible; this is a great mistake. To see a 20 ft. picture in comfort, a person must be at least 20 ft. from it, consequently those in the front are often in the worst position, while those at the back, who generally pay the least, see best. The picture should be as small as possible, provided it can be seen distinctly from the back of the hall.

Having fixed the screen or decided upon its position, the supply of house-gas, if the blow-through jet is used, is generally the next difficulty, and very often the position of the lantern depends upon this. When using mixed gases from cylinders, the lantern can be placed almost anywhere, but with bags it is best to show from the ground-floor, as few galleries have a safe place on which to fix the pressure boards.

The lantern should be supported at such a height that it can be manipulated in comfort. The cylinders should be laid on the floor unless there is something substantial to which they can be tied in an upright position.

The slides must be carefully arranged by the lecturer and operator, and placed in a convenient position, so that they can be reached without much stooping or turning round.

The lantern being on its stand, connect it to the gas supply, turn on the hydrogen and light up, adjust the bypasses, turn on the oxygen, and try the bypasses again; if the gas splutters, cracks, or goes out, look for a leak near the chamber, which must be immediately stopped by sewing up the collar holding the nipple, or the jets will be destroyed, and perhaps the lantern set on fire. The lights sometimes pop out because the bypass flame is not high enough, or because the oxygen bypass is on in the case of the mixed jet.

Open all the front shutters and remove the diaphragm entirely from the lantern, put a focussing slide in the top

lantern and focus as near as the light will allow, remove the slide, and centre the light, turn it down and proceed the same with the middle and bottom ones; next get the two or three discs coincident by the registering templates, and adjust the diaphragm if it is adjustable. All these adjustments occupy an experienced operator about five minutes, and require about half a foot of gas; the amateur may expect to take about ten minutes to do the same work and consume gas in proportion. When using a lantern with adjustable stages, see that the slides are in the centre of the condenser, or the corners may be cut off. When once the lantern is made ready, the adjustments should not be touched if it is possible to avoid doing so; it is better for one or two pictures to be out of the centre, or even out of focus, than to run the risk of spoiling the registration by constantly fidgeting with the screws. Unless the operator is fortunate enough to possess very good eyesight, he will find it convenient to use an opera glass. When using mixed gasses some authorities recommend using house-gas to warm the limes and condensers with a view to economising the hydrogen, and then just before the exhibition begins connect the jets to the bag or cylinder; this is not a safe practice, as there is the liability of getting the oxygen in the gas mains, which is inconvenient even if nothing further happens than the extinguishing of the gas jets in the hall.

When the lantern is quite ready the jets can be turned out by the taps on the supply tubes, or if there is a longer time than say ten minutes before the exhibition begins, the gas had better be turned off at the bag or bottle as well.

To begin, a curtain slide should be placed in the bottom lantern, or centre one in the case of a triple, and the light turned up, the front shutter being closed. "Good evening," or similar one, is placed in the top lantern; the diaphragm should be raised to clear the lantern having the curtain in it. Flash on the curtain by suddenly opening the front shutter, taking care not to jar the lantern, and turn on the top jet. At the proper signal lower the diaphragm, which raises, or appears to raise, the curtain. When a triple is used, the third slide is placed in the bottom lantern and the dissolver used to change the picture, when the diaphragm can be entirely removed; but with a biunial the third slide must be placed in the bottom lantern and the diaphragm raised; the top lantern is then turned off, the diaphragm removed, and dissolving proceeded with.

Some system of signalling, the simpler the better, should be arranged between the lecturer and operator; the following will generally suffice:—Coloured light, "Next picture;" coloured light shown two or three times, "Bring on effect;" coloured light quickly flashed many times in succession, "Picture out of focus;" the bell signals would be the same, but should only be used in the case of the operator going to sleep, and even then it should be muffled. Nothing is more annoying to a conscientious operator than to be spoken directly to by the lecturer, or for the latter to continually find the picture changed at the wrong time, or for it to be out of focus. It ought to be very simple for the lecturer to convey his wishes by introducing a little gag; and as few operators are infallible, any mistake, such as winding the snow up instead of down, should be immediately covered by the lecturer making some remark upon the erratic course of a snowstorm during an east wind in January, or something similar; as a rule an apology only makes matters worse.

A single mistake, provided it is rectified at once and not repeated, will always be forgiven by a general audience. The shutter of the lantern should be closed after the light has been turned down and before the slide is removed, or the afterglow on the lime will fog the picture. This applies especially to blow-through jets. Turning the lime answers

the same purpose, but this cannot always be done if several pictures are shown in rapid succession.

It is always advisable to have an interval of five or ten minutes, to give the lecturer a rest and the operator a chance to clear up his slides and see to his limes, gas supply, etc:

(To be continued.)

#### THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE technical meeting was held on the 28th ult., Mr. W. Bedford, in the chair. The Hon. Sec. passed round prints and negatives taken with the new "Sandell" plate of Messrs. Thomas and Co. Some of the negatives had one or more of the films partially removed to demonstrate the multiple film. He remarked that Messrs. Thomas claimed that owing to the thickness of the film and its multiple character very great latitude in exposure was permitted. Mr. Mackie read an extract from a pamphlet respecting the new plate, and the Hon. Sec. said he had made some sensitometer tests with the plates, which gave No. 25, his highest square. He had also given three or four times the ordinary exposure, and still found gradation from the first number. There was plenty of light-absorbing power in the films for a far denser image than would ever be needed. Mr. Cadett said the plates certainly had good qualities and could be over-exposed to a much greater degree than ordinary plates without harm. An ordinary heavily-coated plate, however, would yield gradation far beyond anything which an ordinary printing process would show. The Hon. Sec. thought if a negative with a large range of gradation were developed thinly enough, the whole range might be shown in the print. Mr. Cadett said only to a certain extent. In a negative thin all over the gradations near the shadows would have no printing value, so that what was put on at one end was taken off at the other. In reply to a question from the Chairman, the Hon. Sec. said a "Sandell" plate might show all the gradations on a sensitometer screen, but the difference between one square and the next would be proportionately smaller. Mr. Debenham remarked that as far as his experiments went, when a plate had been exposed to such an extent that with an ordinary developer it would reverse he had not been able by any variation in the developer to prevent that reversal. Mr. Clifton said he had made the same observation, however much the developer was restrained. The reversal showed as soon as development was commenced. Mr. Debenham said there had been a good deal of experiments years ago in mixing emulsions of quite different rapidities. He did not know whether any definite result was arrived at as to whether greater range of gradation was thus obtained. Mr. J. D. England said with mixed emulsions there was a loss of gradation. Mr. Cadett remarked that the supposed result of mixing a slow emulsion with a rapid one was a mean of the two, but actually the result favoured the slow emulsion rather than the quick one, and you got the bad qualities of both. Mr. Mackie pointed out that in an article which appeared about a year ago, Prof. Burton said he had found great advantage to arise from mixing emulsions. The Chairman thought as reversal could be encouraged by modification of development; it might also be retarded, although the method was not yet discovered. Mr. Mackie said Col. Waterhouse's experiments certainly proved that a plate only sufficiently exposed to produce a negative could be made to produce a reversed image. Mr. Bolas thought the use of bichromate did not so much encourage reversal as tend to make it a little more definite than it would otherwise have been. By the use of bichromate it seemed to him very easy to get complete reversals, although a longer exposure was necessary than without the bichromate. As far as he could judge, negatives produced on bichromated gelatine plates could be made identical with the originals. The Hon. Sec. remarked that Bennett had found complete reversal by an exposure of about ten times that which gave the maximum deposit, using a pure gelatino-bromide emulsion. Iodide in an emulsion appeared to very greatly retard reversal. The meeting then terminated.

**Belfast Y.M.C.A.**—On the 4th inst. the usual monthly meeting was held, Mr. W. Pollock presiding. The prints in the Monthly Competition were on view, the awards having been made as follows: First prize, J. McCleery, for an artistic study of a group of sheep standing in a country lane, the tone of print being a rich brown colour; second place was secured by J. A. Pollock, "On the River Bank," a pretty scene, several cattle well grouped, giving great effect to the picture; third place to W. H. McCleery, a view at "Red Bay," near Cushendall. Samples of the new Eastman gelatino-chloride paper were distributed; finished prints on same were shown by the Secretary and passed round for inspection, the tones ranging from sepia to a rich brown.

# W. WATSON & SONS, 313, HIGH HOLBORN, LONDON,

HAVE RECENTLY BEEN AWARDED

At the **AMSTERDAM** PHOTO EXHIBITION, 1891—THE **MEDAL OF THE SOCIETY**

At the **GLASGOW** PHOTO EXHIBITION, 1891—THE **MEDAL OF THE SOCIETY.**

At the **ANTWERP** INTERNATIONAL MICROSCOPIC EXHIBITION, 1891—TWO **DIPLOMAS OF HONOUR**  
(Degree above Gold Medals).

At **BUDAPESTH**—THE **GOLD MEDAL OF THE PHOTOGRAPHIC SOCIETY.**

Making 27 awards for the excellence of their Instruments, including Paris Universal Exhibition, 1889 (2 Gold), London, Liverpool Melbourne, etc.

W. WATSON & SONS believe they are the largest Manufacturers of High-class Photographic Instruments in Europe, and intending Purchasers can be allowed at any time to inspect their Steam Factories, which are close to their Warehouse, and judge for themselves as to the quality of Material used and the care bestowed on the Manufacture of their Goods, which W. & S. are confident is elsewhere unequalled. *Testimonials as to the efficiency of their Instruments are received almost daily.*

## Watson's "Acme" Camera.

Unsurpassed for Outdoor use.

## Watson's "Premier" Cameras.

For Professional use, *Indoor or Out.*

## Watson's Studio Cameras, Tripods, Enlarging Lanterns, etc.

## Sensitized Albumenized Paper.

The Best White or Rose. Per quire, 13s.; half quire, 6s. 6d.; quarter quire, 3s. 6d. Single sheet, 10d., post free.

AN ILLUSTRATED CATALOGUE OF CAMERAS, LENSES, AND APPARATUS SENT FREE TO ANY ADDRESS ON APPLICATION. Established 1837.

— AND AT MELBOURNE, AUSTRALIA—251, SWANSTON STREET. —

STEAM FACTORIES: 9, 10, 11, 16, and 17, FULWOOD'S RENTS, HOLBORN.

## Watson's "Detective" Hand Camera.

## Watson's Rapid Rectilinear Lenses.

## Watson's Wide Angle and Single Landscape Lenses.

All Cameras and Lenses may now, at an advanced cost, have the Metal parts made in Aluminium.

## Sensitized Matt-Surface Paper.

Exceedingly popular. Yields most artistic results. Per quire, 13s half quire, 6s. 6d.; quarter quire, 3s. 6d. Single sheet, 10d., post free

# Wratten & Wainwright's CELEBRATED "LONDON" PLATES,

"ORDINARY" (15°). For Landscapes, Copying, and Transparencies.

"INSTANTANEOUS" (19°). For Studio and General Work.

"DROP-SHUTTER SPECIAL" (24°). For Dull Weather and Hand Cameras. The most rapid Plate made.

Have been manufactured continuously for fifteen years, and have never yet been approached in quality. They are recognised by the most competent authorities as the standard by which all other Plates are judged. These Plates are indispensable for the production of Exhibition Pictures. More High Class Medals have been secured by results on the "London" Plates than all others combined.

# Wratten & Wainwright's SENSITIZED PAPER

HAS THE LARGEST SALE AND HIGHEST REPUTATION, KEEPS WELL,  
TONES EASILY, AND DOES NOT BLISTER.

## UNSOLICITED TESTIMONIAL.

"Messrs. MARION & Co.,

"Haileybury College, Hertford,

May 24th, 1892.

"I wish to take this opportunity of saying how much I have benefited by the Actinograph. I have had a great deal of copying prints, etc., to do in a room here, and after one or two experiments to decide on the special factor necessary under the conditions, I settled down to be guided entirely by the Actinograph as to exposure. Out of the 300 or 400 negatives I have thus taken, I have had so few failures that I attribute them entirely to my carelessness. Yet I have followed the Actinograph in all conditions of weather, and at all times of the day, from January to May, with plates of different speeds, and with varying stops. I have had but little experience out of doors with it. What I have had has been as satisfactory as indoors.

"I am, yours faithfully, Rev. W. D. FENNING, M.A."

## A Holiday in Norway.

PHOTOGRAPHY AMONG THE FJORDS.

(Continued from page 28.)

### IV.—MUNDAL AND BALHOLM.

A PEEP AT TWO GLACIERS.

THE morning found us lying off the hamlet of Mundal, in the Fjærlands Fjord, the Boiums Glacier gleaming white in the sun over the sloping shoulder of a great hill away to the northward. We were very quickly on shore, and perhaps more photographs were taken here than at any other place where we touched. Without moving more than a score of yards it was possible to get some half dozen magnificent views of the fjord, which here widened into a placid lake, in whose still depths the ship lay mirrored, and of the ring of mountains lying around the picturesque little village; while the verandahs of the hotel afforded a charming background for those who desired to take groups of

far up the hill, the broad white sheet of snow sweeps down, its lower edge of icy blue, broken into deep fissures and crevasses, which lend a tinge of azure to the fringe of snow above. In one of these fissures, the opening guarded by a flying buttress fashioned out of a curving pillar of ice, a remarkable cave is formed, whose walls are all of blue. Inside this cave an admirable photograph of some of the explorers was secured. The Suphellebræ is reached by a softer valley, the hills enclosing which being robed with grass and silver birches. It descends to within 160 feet of the sea level, and the ridges of gravel deposits that one passes mark the limits reached in years gone by. On the way back, as on the road thither, Norwegian maidens stood outside their scattered homes and offered to the thirsty traveller milk just brought down from the *sæters* above, and glasses of home-brewed Norwegian ale. Back at Mundal again, a group of men busy in building a house attracted our attention. The Norwegians are famous for their manual dexterity at all kinds of woodwork, but still it seemed strange that not a single saw or plane was to be found amongst all the workers—no other tool than the axe. Yet the wooden walls of the house were neatly and strongly dovetailed at the angles, and all the work, so far as could be seen, most skilfully and thoroughly finished.

THE ROAD TO THE BOIUMS GLACIER.

their friends. So attractive was the scene, that many of the passengers lingered awhile before starting for the glaciers. It was a lazy day. Mundal lies in a central valley, whence, as the spokes of a wheel, mountain ridges radiate in all directions. The heat was intense down in the valley, and the springing verdure everywhere showed that we had lighted on a most fertile spot. Wandering off along the valley that leads to the Boiums *bræ* or glacier, we found the broken ground between us and the hills simply carpeted with violas and dainty oak and parsley ferns, and many a flower that England does not know. The snow-capped hills on the left, the still waters of the fjord rippling to our feet on the right, the cool vision of the glacier sweep some miles ahead, and many a babbling fall meandering down the mountain sides and through the level rocks, these were the accompaniments of the first part of the walk. Then came the parting of the ways, one valley leading off to the Suphelle, and the other to the Boiums glacier. Here broad meadows spread an emerald floor between the encircling mountain walls, on whose white summits lay the azure roof unflecked by any cloud. Hence the Boiumsdal proceeds at first through groves of flickering sun and shade, and afterwards between dark cliffs along the side of the foaming, ice-cold glacier stream. The *bræ* is in sight the whole way, but it is a long and a stiff walk right up to it, yet one is sure of one's reward. From

### ON THE WAY TO BALHOLM.

The attractions and the excursions of Mundal were not yet nearly exhausted, but some of us had a desire to visit Balholm at the entrance to the Fjærlands Fjord. So about half-past four we secured a boat with two rowers who agreed to take us the sixteen miles down the fjord. That run down to Balholm none of us who took part in will ever forget. A perfect peace, born of the perfect summer day, breathed on the quiet hills that lay steeped in the sun's warm glow. The tiny rills scarce seemed to move, except to make that music which

"brings sweet sleep down from the blissful skies."

Not a cloud broke the blue above, and far ahead the shining waters slept, wakened for a moment by the dipping oars as we passed on smoothly gliding keel, then falling into silver sleep again. The sturdy boatmen swung in perfect rhythm as they bent to their task, and sang as they swung fragments of the Balder Saga, and of quaint Norse airs, while we lay at the bottom of the boat, and, like the Lotos-eaters, thought—

"How sweet it were, hearing the downward stream,  
With half-shut eyes ever to seem  
Falling asleep in a half dream."

Four hours of this, and then passing the mouths of the Vetle and

Svær Fjords, the promontory on which Tjugum is picturesquely built was rounded, and Balholm lay full in view, one of the loveliest of all the villages on the Sogne Fjord. A legendary interest attaches to it too, for Balholm and Vangsnaes, on the opposite shore, are famous as the scene of Tegner's beautiful "Frithiof Saga," which is shortly outlined in Edna Lyall's book, "The Hardy Norseman." Right before us, as we landed, stood Herr Kvikne's Hotel, the most comfortable and homelike to be found in all Norway. In front of the verandah, which is but a few feet from the water's edge, rose rich clusters of white and purple lilacs, whose breath filled the air with balm; and near at hand was an orchard piled high with masses of snowy and crimson bloom. Behind the hotel Munkeegen and Tjugum-toten lifted their snows to the skies, and before us, across miles of shimmering water, rose another lofty range. Round to the right curved the sloping shore with its fringe of sentinel trees, and behind these white and red houses cosily set in verdant fields at the mountain's foot. From the wooden quay in front of the hotel, a bridge led over to a tiny island, where excellent baths had just been built, and within a stone's throw of the orchard was a passable tennis ground. These things we saw nowhere else; but Balholm, surrounded as it was

broken by the carol of a sweet-voiced bird. What the difference was no one could tell, but there was a change, and night had passed into morning. The clear, cold light of dawn stole over the fjord, coming from the east, and struck on a mountain peak 4,000 feet high; and soon, on the milk-white snow that rose from its broad bosom about its rocky head, one little ray of sunlight fell, and lay there like a blush rose newly blown. Then with rosy fingers came the morn and took the rose and flung it all abroad, and bathed the hills in glowing light, and leapt up to the sky and faintly crimsoned the cloudlets there. All around broke forth the song of the birds;

"The cuckoo told his name to all the hills;"

the thrush sang loud as if he were in an English garden, and "sang his song twice over,"

"Lest you should think he never could recapture,  
That first, fine careless rapture."

A brown-sailed boat put slowly out from the harbour and sluggishly moved across the shining fjord, and soon over the wooded shoulders of the hills round Tjugum rose the smoke of the *City of Richmond* coming to pick us up. Seeing this, and

MUNDAL (from the "City of Richmond").

by magnificent scenery, had yet a cosy and prosperous air. The houses were larger and better built. The inhabitants all seemed well-to-do, and yet they retained sufficient curiosity to wait up all night to see the great ship that was to call for us in the early morning on its way from Mundal to Gudvangen. Here it was that one of the most remarkable photographic feats of the trip was attempted. In the middle of the village is a mound, marked by a monolith as the grave of King Bele. Just after midnight, for the ship was late, an enthusiast of the camera, and a Scotchman to boot, conceived the idea of photographing the mound and the group of Norse lads who stood on the top of it. An exposure of a minute and a half was given, and as soon as he had removed the cap, he actually came round and joined those of us who were standing in the foreground. At the end of nearly a minute, the natives grew tired of the silence and coolly walked off in a body. Still our amateur calmly waited, and at last walked up to the camera and replaced the cap, dismissing all irregularities with an off-hand, "Eh, mon! it's a' richt!" A day or two afterwards, however, he confessed that the plate was "a failure so far as a picture was concerned."

#### SUNRISE ON THE MOUNTAINS.

Still the steamer did not come. But waiting in the warm, still air of that balmy night, so light that it seemed only a dull afternoon, was easy; and presently, as we waited, a breeze of morning stirred amongst the leaves, and the hush of silence was

obedient to the warning whistle that shook the morning air, we rowed out to meet her, followed by a small flotilla of Balholmmites, bent on seeing all they could of the monster ship.

(To be continued.)

### Societies' Meetings.

**Eastbourne.**—Ordinary meeting on 6th inst., about twenty-five members present, Rev. H. G. Jameson in the chair. The Secretary (E. Burnham) announced that Capt. Brand, the Liberal candidate for the division, had allowed himself to be proposed as an hon. member. Dr. Habgood continued his lecture, commenced in May, descriptive of a tour in Spain and the South of France. The photographs were uniformly good, considering the difficulties under which he laboured. In Paris the worthy doctor was nearly arrested through not having obtained leave of the police to photograph; he was locked up in the Mausoleum at Nimes, and had to clamber over the railings, and in Lisbon he had to keep one eye on the camera and the other on the police. At the conclusion of his lecture Dr. Habgood showed some hand-camera work done at the Zoological Gardens on the occasion of the recent excursion of the Natural History Society to that institution.

**Hackney.**—The usual meeting was held on the 5th inst., Mr. Walter Barker in the chair. The Chairman on rising was warmly greeted, and, in the course of a homely little speech, hoped the new quarters would be fully appreciated. A question from the box about

whether carbonate of potash would frill more than ammonia was then discussed. Mr. Beckett had never had any frilling with either; possibly the temperature of the water was the cause. Mr. W. Fenton-Jones said soft gelatine used by some makers was sometimes a cause. A question was then asked, "If two lenses of the same focus were selected for use in stereo work would they be suitable, and would there be any difficulty of letting off shutters at same time?" Mr. Dando said there would be no mechanical difficulty, but the lenses ought to be good, and selected by an optician. Mr. Sodean showed card indicating the 100th, 200th, and 300th parts of an inch. Report of excursion was then taken, Mr. Gosling humorously describing it. Mr. Dean showed photograph of fungi  $18\frac{1}{2}$  inches across; Mr. Barker work done on Eastman's gelatino-chloride paper, samples of which had been sent. Mr. Dando handed round a piece of the same paper, which he had put in wrong way in frame, and asked if he dissolved the gelatine from other side would it fade? Mr. Beckett said not, if paper had been properly fixed and washed. Mr. Gosling handed in prints on Ilford P.O.P., Ilford Iso. plates. Mr. Hudson showed an arrangement he had made, on the stereoscopic principle, for taking any moving objects. The idea was that focussing could be done on the top, and the exposure made immediately it was obtained sharply. Mr. Dando thought the top would rather draw out of focus. The Chairman showed a diaphragmatic shutter, the shutter opening from and closing to any sized diaphragm. It was said that the principle was wrong, as only 50 per cent. of exposure was obtained. Mr. Hensler had heard it stated that a smaller stop alters focus. The Chairman observed that Dallmeyer advocated focussing with any aperture but the full. Mr. Beckett said faulty lenses would alter in focus. The Chairman handed round a new hand-camera of his own design. The plates dropped on to an india-rubber band, which one member declared was dangerous to the plates, as it would cause a formation of sulphur. Mr. Dando wanted to know whether storing backed plates would cause them to deteriorate, but an opinion was that it did not. Mr. Dando was then unanimously chosen as a delegate to the Convention on behalf of the society. Mr. Wheeler was nominated.

**Harlesden and Willesden.**—A meeting was held on the 5th inst., J. Naylor, Esq., in the chair. The minutes of the last meeting were read and approved. The following gentlemen were elected members:—Messrs. C. F. Mitchell, R. Schofield, and R. J. Houlton. Records of two previous excursions were read by Mr. Naylor and Mr. Woodbury. The decision of a room for holding the Society's meetings was left in the hands of the Council. Mr. Naylor then gave a demonstration of the new cold-bath platinotype process. After a short *resume* of the history and chemical theory of the process, he proceeded to show the superiority of the new process over the older ones. The printing, he explained, required to be carried on until the image was more visible than with the old process. The members then adjourned to his palatial dark-room, when a practical demonstration of the development took place. The members were much interested in the manner of development, and the methods shown of saving an over-exposed print, or by the addition of glycerine to the developer, over-developing certain portions stronger, in order to gain greater contrasts when required. Referring to the methods of obtaining sepia tones with the aid of uranium and other metals, Mr. Naylor reported a discovery of his own, which he practically demonstrated, for obtaining sepia and other warm tones by the addition of a small quantity of bromide of potassium to the developer. A discussion then followed, and a vote of thanks was passed to the President for his able demonstration. The Secretary then handed round some remarkable instantaneous photographs taken on Paget xxxxx plates, giving a fair example of the excellence of these plates for instantaneous work. An excursion to Pinner, under the leadership of Mr. Clapton, was arranged for the following Saturday.

**Kensington and Bayswater.**—A meeting was held on 11th inst. There were present Mr. T. A. Hahn (in the chair) and seventeen other gentlemen. Mr. Sydney Mote gave a conjuring entertainment, filling the audience with astonishment at the wonderful feats of legerdemain. Mr. G. W. Tottem, from Messrs. Houghton and Sons, gave a practical demonstration on their excellent little hand-camera, called the Shuttle, and various other novelties. Mr. Winter, from Messrs. Mawson and Swan's, kindly showed the Loman patent camera, a novel form of book-camera, walking-stick tripod, etc.

**Leytonstone Camera Club.**—The members of this club had a most successful outing on the 2nd inst. The place of meeting was Kingstons Station. Some good shots were got in the town, it being market-day. The busy market was well patronised by carriers of hand-cameras. The coronation-stone and other historical spots having been visited, the party were ferried over the river, where points of vantage were secured for the bridge and town. The bridge was next crossed, and the party proceeded to the promenade, where some excellent snap-shots on the river were made. Proceeding along to Teddington, some good shutter exposures were made: "The Lock," "Going over the Rollers," "The Weir," etc., etc. The party then adjourned to the "Jolly Anglers Hotel" to a capital tea. The

muster was here photographed by one of the members, and a move on to Teddington Station was made. The weather having been splendid all day, the excursion was most enjoyable, Leytonstone being reached about eleven o'clock. The next outing is on the 16th inst., to Cheshunt; meet at Cheshunt Station four o'clock. Visitors heartily welcome.

**Lewes.**—A meeting was held on the 5th inst., when a small exhibition of hand-cameras was held. Some of the members described the cameras they had in use, and Mr. E. J. Bedford gave a description of several of the latest patterns, which had kindly been lent by Mr. Harcastle, of Brighton. The certificate for the last quarterly competition, for "the best photograph of animal life," was awarded to Mr. J. Tunks. Mr. Foxhall (Brighton) judged the prints sent in, which were not so numerous as might be desired. The society will make an excursion to Alfriston on Saturday if the weather is favourable. Others have been arranged for Buxted, Newick, and Isfield. The subject for next quarterly competition is "Landscape, with or without Figures." Mr. J. L. Adam was elected a member of the society.

**North London.**—On the 5th inst., Mr. B. J. Grover in the chair, received with thanks for library, Mr. E. Dunmore's "The Photographer's Companion," Mr. J. Fallowfield's "Photographer Annual." The Secretary reported that he had received a very kindly letter from Mr. J. Howson, of the Britannia Works Company, Ilford, who was to have addressed the meeting on "Isochromatic Photography," stating that he had been called abroad at a few hours' notice on urgent business, and would be unable to be present. The Company had, however, sent as a substitute a large parcel of their new Isochromatic half-plates for distribution among the members, who it was hoped would test and report upon them. Notice of the change of programme had been sent to all members, and a general conversation on technical matters took place, principally on Isochromatic plates. Mr. Brewer showed a successful negative of red roses taken on these plates, and the Secretary, who used hydroquinone (Ilford universal) as a developer, had found the Isochromatic plates most useful. Other members preferred a pyro developer, but all who had tried agreed in the great advantage of the colour correction. The plates received were duly distributed as requested.

**North Middlesex.**—On the 11th inst., Mr. C. C. Gill in the chair, a technical evening was held. In the unavoidable absence of Mr. F. W. Cox, Mr. F. Cherry opened the discussion on "Development." He dwelt chiefly upon the portraiture side of the question, gave his own method of working, and dealt with the allied subjects of lighting and exposure. Messrs. Beadle, Frost, Marchant, Smith, Taylor, Wall, Mattocks, Tittensor, and the Chairman took part in the discussion, which gradually tended in the direction of the prevention and cure of halation. The comparative difficulties and advantages connected with working celluloid films also attracted attention. Some of the members had found a difficulty in washing film negatives when a number had to be treated at once. Mr. Frost had solved the difficulty by bending the film into a cylindrical form, gelatine side inwards, and tying it round with a piece of thread. A number of them could then be put into a washing trough, and the water allowed to flow through them without fear of injury. They were then hung up to drain in the same state, and when dry the thread could be taken off. Three new members were elected. Prints were then shown as examples of the Eastman gelatino-chloride paper which were distributed at the last meeting, the consensus of opinion being that the paper was good in all respects, and that widely different tones could be secured upon it with certainty and ease. The usual competitions of views taken at field-days were held, the vote of merit being accorded to Mr. Marchant for Broxbourne, and to Mr. Walker for South Mimms. The next meeting will be held on the 25th inst., when Mr. F. Cherry will take the chair, and Mr. Thomas Bedding will address the society. Visitors welcome.

**Sheffield.**—The ordinary monthly meeting was held on the 5th inst., Mr. B. J. Taylor in the chair, when after the usual routine business of the meeting, and the election of two new members, Mr. C. W. Crowder gave a paper, subject "A Holiday Tour on the Norfolk Broads." He began by describing the journey to Yarmouth, and from thence to various resorts on the Broads, also the best and most convenient means to get there. He had brought back with him some splendid pictures, showing his success, and the grand scenery to be met with all along the district. The Secretary laid on the table samples of the new Eastman's printing paper, also two new photographic journals, and intimated that the excursion to Allport next Wednesday gives promise of a large number taking part in the same.

**South Manchester.**—On the 27th ult., Mr. W. I. Chadwick in the chair, exhibits of holiday work were brought by Messrs. Bowden, Linnell, Wood, and others; questions were replied to as to toning, etc., of these exhibits. Mr. M. W. Thompson (Hon. Secretary) read a short paper on the "Platinum Process of Printing," and gave a practical demonstration of the new platinotype paper, in the course of which he showed that prints could be developed by going

over them with a brush charged with the potassium oxalate solution, or by floating, or immersing them in the ordinary way. Over a dozen pictures were thus produced, which were to be preserved in the society's technical folio. After the demonstration many questions were replied to, and various experiences given. Mr. W. I. Chadwick read a paper on "The Magic Lantern," and exhibited a Sciopticon in operation, with a transparent screen made to roll up into a very small space, and supported by a pair of portable legs; the whole of the lantern and screen could be placed on a dining-room table, exhibiting a 3 ft. 6 in. picture, which was considered large enough for most private house exhibitions.

**South London.**—Ordinary meeting on the 14th inst., the President, Mr. F. W. Edwards, in the chair. Attendance, thirty-three. At the conclusion of the formal business, Mr. J. F. Kelly read a paper, "Can our Excursions be made more Interesting and Useful?" After a brief description of a typical photographic excursion, the lecturer dealt with a large number of suggestions for rendering such meetings more attractive and useful. He considered that excursions should always be arranged to suit the pockets of the majority of the members, and suggested that at the commencement of each excursion a short demonstration by some competent member nominated for the purpose of the practical use of some part of our apparatus in the field, as the proper use of the rising front and the swing, the capabilities of lenses, exposure, and the uses of tables and meters, shutters, etc. He regarded excursions as a means of educating the younger and inexperienced members of the Society, while the more competent workers would use them as prospecting times for more serious work. The announcement at the preceding meeting of the places to be photographed and the points of interest, etc., would be useful. The social side was dealt with. The lecturer urged that excursions should be arranged with some end in view, as, for instance, the illustration of the river Thames from Sheerness to Oxford, a complete series of local views, the monuments of London, etc. Results should be shown at the following society meeting, and a free and impartial criticism indulged in and advice and suggestions given. Mr. Kelly deprecated the practice of stowing away good negatives until the exhibition, for fear that some brother worker might infringe his copyright. The view was not made by the first man, that is common property, and the mind might not be able to so arrange it as to make a picture, or might make a better than if he deserved the credit of it. A set of good lantern slides, illustrating the excursion, should be made yearly, to become the property of the Club, and loaned to members after they have been exhibited at a meeting to be held for the purpose. This meeting might be so arranged as to form a general entertainment by the members, and be productive of general good feeling. Mr. Kelly's remarks were criticised at great length by the members present.

**Southsea.**—At the ordinary monthly meeting held on the 6th inst. the rules of the forthcoming exhibition to be held in October were drawn up. There was a large attendance of members to hear the announcement of the judge's awards in connection with subjects obtained at the recent excursion to Bosham. Two prizes had kindly been offered by the President (Mr. J. J. Thornton) and the Vice-President (Dr. Ford) for genre subjects and landscapes respectively. Forty-two prints were entered for competition, and were kindly judged by Mr. H. Symonds, of Portsmouth. His awards were as follows:—*Genre subjects*: first, Major Bruno; second, Mr. Ward; third, Mr. Sawyer. *Landscapes*: first, Mr. Fisher; second and third, Mr. Grant. The whole of the prints were passed round for inspection, and were accompanied by the judge's note criticising the work. Several new members have recently been elected, and the society is in a flourishing condition.

**Tunbridge Wells.**—The ordinary meeting was held on the 7th inst., Mr. Ernest R. Ashton in the chair, the chief feature for the evening being the inspection of some hand-cameras, which had been kindly sent down by the makers for that purpose. Unfortunately, several which had been promised did not arrive, from some unexplained cause. There was a good attendance notwithstanding it was the eve of the election and two very important meetings were to be held by the candidates. Messrs. Marion and Co. sent down one of their "Radial" hand-cameras; the changing arrangement from which it takes its name, and by which any plate can be exposed at will, is very good, and the shutter is arranged so that it can be set whilst the plate is in position. Messrs. Shew and Co. sent down a good assortment, comprising their Academy Eclipse, their half-plate Eclipse with swing front, also another same size with swing back, and an Eclipse with a Ross Eclipse lens working at  $f/5$ ; one of their Universal cameras, arranged as a hand-camera or for ordinary work; one of their Guinea Eclipse hand-cameras, with three double backs and a repeatograph; this is one of the Magazine type, all the others before mentioned having double backs. Messrs. Dunkley and Rogers sent a "B" daylight Kodak; this is one of the Eastman Co.'s new series that allows the spools to be changed in daylight. Mr. Lewis brought a Facile, the Chairman a No. 3 Junior Kodak, Mr. Morgan one of his new hand-cameras, with a novel

focussing arrangement, no cloth being required, Mr. Cassingham also brought "The Surprise," Tylar's "Tit-Bits," Stern's Stereoscopic, The Pearl, and Smith's Patent. Some prints were shown, the result of the excursion to Crowborough. Samples of the Eastman gelatin-chloride printing paper were distributed.

**Admiral Mouchez**, the President of the Photographic Astronomical Congress, and President of the survey of the heavens, is deceased.

The competitions of our contemporary *Science Stiftings* have received very wide support, and several well-known workers have been successful in carrying off the prizes.

**Mr. J. M'Cleery**, Hon. Secretary of the Belfast Y.M.C.A. Camera Club, requests us to notify that all communications should be addressed to him at 14, Wellington Place, Belfast.

The editorial offices of the Optical Magic Lantern Journal have now been removed from Salisbury Square to 55 and 56, Chancery Lane, W.C. Mr. J. Hay Taylor, the well-known editor, will be pleased to see any visitors at the new address.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by **TUESDAY MORNING'S POST**.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

## QUERIES.

5752. **Burnishing.**—Can any of your readers tell me how to burnish photographs, and what substance to put over the print before passing it through the burnisher? I soak Castile soap and methylated spirits together and cover the print, and when dry I pass it through the burnisher, and I have to pass it through about five or six times before I get a good burnish on it, and the heat I have the rollers is just hot enough for anyone to bear. I shall be much obliged if some of your readers will let me know my difficulty and cause.—S. L. W.

5753. **Whitby.**—I shall be much obliged if any reader will inform me whether there is a dark-room available for visitors at Whitby. If so, please give particulars; also, can one obtain Ilford plates there?—H. W. A.

5754. **Photo-Micrography.**—Will any reader kindly help me with suggestions as to photographing of yeast under the microscope? Hints as to size of objective, kind of light, exposure, and development gratefully received.—E. W.

5755. **Black Varnish.**—Can any reader give me a good formula for black varnish for backing positives?—BLACK ART.

5756. **South Devon.**—Can any reader put me in way of obtaining photographs of the old timber viaducts on the South Devon Railway between Brent and Cornwood stations? With the exception of the Blackford Viaduct, these picturesque relics of the past all have new granite viaducts built alongside of them, and are hardly worth photographing now. The condition of the Blackford Viaduct is rather more favourable at present, but I should prefer to have a view of it taken two or more years ago, before the doubling of the line was commenced.—BEDFORDSHIRE.

5757. **Bournemouth.**—Could any amateur tell me if there is anything in or near Bournemouth worth photographing, as I am going there early in August for a month?—BANTY.

5758. **Washing Prints.**—At the house where I live there is no tap water laid on, the only supply we have being a pump in the yard, and when I am toning prints I have to go out and pump on them to wash them, and again I have always to do it at night, and if I have, say, a dozen prints and got to go and pump on each one, it is very tiring, and one does not much care about it. Can any fellow reader tell me of any way whereby I could tone and wash prints without having to go and pump on them to wash them? I shall be obliged for any suggestions.—ANXIOUS ENQUIRER.

5759. **Weston-super-Mare.**—Can any reader give me any information about photographic bits near this place? A short resume of the best bits in the neighbourhood would be appreciated.—NOBBY.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## ANSWERS.

5740. **Wratten Plates.**—Mr. Watkins' latest speeds for the Wratten plates are 8, 40, and 45, or in exposures, ordinary, 55; instantaneous, 14; drop shutter, 1. From our own trials we consider these right.—EDITOR.

5742. **Ross.**—Having the lens, could you not try which stop should be used? If we recollect right, the No. 2 c. de v. will cover a half-plate, or only just cut off the corners; but how small a stop you must use to obtain sufficiently marginal definition is a matter which you must decide for yourself.—EDITOR.

5745. **Touring (Kent and Sussex).**—Falstaff Hotel, Canterbury; Queen's Arms Hotel, Margate;

Bell Hotel, Sandwich; C. Stewart Dunn, High Street, Deal (keeps plates); Royal Oak Hotel, Dover; W. Percy, Leicester House, Grace Hill, and London and Paris Hotel, Folkestone; A. Brooker, 52A, Robertson Street (keeps plates), and Waverley Hotel, Havelock Road, Hastings; Castle Hotel, London Road, Tunbridge Wells.—FRANK LITCHFIELD.

5745. **Touring (Kent and Sussex).**—C. Smith will find dark-rooms in the places named as follows:—Canterbury, W. Pollard, 53, George Street; Margate, W. S. Harvey, 20, Market Place; Ramsgate, E. Baily, 9, Queen Street; Dover, J. G. Whorwell, 7, Bench Street; Sandgate, W. H. Jacob, 3, High Street; Hastings, A. Brooker, 52A, Robertson Street; Eastbourne, J. G. Flatman, 40, Pevensey Road; Tunbridge Wells, B. Whitrow, 15, St. John's Road. In addition to above, Birchington-on-Sea, Deal, and Folkestone are included in the AMATEUR PHOTOGRAPHER "List of Dark-Rooms" (August 7th, 1891), the names of which are not published, but letters of introduction to which are to be obtained on application to Editor of AMATEUR PHOTOGRAPHER.—W. A. W.

5746. **Fixed Focus.**—"Fra" should have given the focus of his lens, as it is not sufficient merely to know that it works at  $f/8$ . The rule is that if we allow the maximum permissible disc of confusion to be 1-100th of an inch, then the distance in yards beyond which all will be in focus =  $2.7 \times \frac{a}{f} \times f^2$  ( $f$  being expressed

in inches). As the lens is to work at  $f/8$ , then  $2.7 \times \frac{1}{8}$  equals nearly  $\frac{1}{3}$ , so the distance in yards is approximately equal to  $\frac{1}{3}$  of the square of the focus. As "Fra" does not state his focus, I can only say, as he speaks of quarter-plate, it will probably be from 4 to 5 in., in which case if 4 in., the distance would be 5 yds. 1 ft.; if 4½ in., about 7 yds.; and if 5 in., 8 yds. 1 ft. As regards distance from lens to ground-glass, that will again depend upon focus, but with a 4 in. lens it will be 4-12 in. very nearly, and with 5 in. lens 5-12 in.—W. A. W.

5747. **Stops.**—Either Lancaster, Birmingham, or Henry Park, Acton Street, Kingsland Road, London, would supply these, as they are makers of all sorts of camera fittings and brass work. Focus of lens would have to be quoted, otherwise it would be impossible to calculate correct ratios. The price is not given in their lists, but I believe it would be about 2s. 6d. But has not "Diaphragm" sufficient ingenuity to cut stops out of ferrotype plate, blackening, of course, afterwards with dead-black varnish, or even at a pinch, out of cardboard and blacken with Indian ink?—W. A. W.

5749. **Distance.**—Everyone has the same difficulty. Distance affects the lengths of exposure, so if you correctly exposed for the foreground you would greatly over-expose for an extreme distance, in the same view, of four miles. There has, however, been put on the market lately a plate having several layers of film on it of progressively slower reaction. This might suit you, if you can develop it right. Your dealer will tell you the name of it.—MORNINGSIDES.

5749. **Distance.**—H. F. B. has probably over-exposed. In working with "Wormald" has he noted following extract from preface? "The exposures given in the index tables will be found to be of average duration for most out-door work, but for open landscapes it may be halved, and quartered for distant views without near foreground," e.g., in July, mid-day, sun shining, slow plate, using  $f/32$  (small stop desirable for such views), I should give 3-8th second, but should prefer diffused light and double exposure. A good plan is for distant views (if camera will admit of it) to employ back lens of R.R. only, which itself would have effect of quartering exposure—so that in that case the tabular times might be used.—W. A. W.

5750. **Holiday Resort.**—I can strongly recommend to "Niepce" Ventnor, Isle of Wight, being both inexpensive and in the midst of most interesting scenery. Distance from London, about 95 miles. Return fare, 18s. 4d. Exposure, being seaside, full, short, say "Wormald's" tables. Places of interest too many to enumerate; Portsmouth and Ryde on journey, Bonchurch, Shanklin, Luccombe Chine, Blackgang Chine, Carisbrooke Castle, Needles, Alum Bay, Cowes, etc., etc. Lodgings very reasonable; can recommend the Clarendon Boarding House, where terms are from 25s. inclusive (card with Editor).—W. A. W.

5750. **Holiday Resort.**—"Niepce" will be charmed if he tries Harpenden for pictures. It is twenty-four miles from London (Midland main line), four and a half from St. Albans. It is a country place, full of lovely bits of inland and river scenery. "Niepce" can obtain comfortable board and lodgings at 2, Church Green, Harpenden, and can have use of dark-room, etc., for about the terms he names.—J. A. W.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S POST if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many

matters have to be left over each week. This we much regret.—ED. AM. PHOT.

U. T. MILLER.—Use  $\frac{1}{2}$  oz. of metabisulphite of potash in each solution, and omit the sulphurous acid and sulphite of sodium altogether.

W. R.—The figures in your view are utterly out of place and incongruous, and the lights in the picture are scattered too much, so that the eye wanders over the print and fails to find any rest. Technically it is quite up to standard. Entry form sent on.

G. P. A.—(1) Over-exposed and under-developed, and printed in too strong a light. (2) Decidedly better, but printed in too strong a light. (3) Under-exposed for the dark shadows on right. (4) Very fine. (5) Insufficiently developed. (6) Printed in too strong a light. (7) Good. (8) Printed in too strong a light. (9) Insufficiently developed and over-printed. (10) Good. (11) Under-exposed. (12) Good. (13) Under-exposed. (14) Printed in too strong a light, and over-toned. (15) Under-exposed for all but the water-fall; printed too deep. Your great fault seems to be over-exposure, or else not continuing development far enough. You do not state what developer you are using. Any gelatino-chloride paper would give you better results; in printing, too, you are using far too strong a light, hence the flatness of your prints. Try printing under one or two thicknesses of tissue paper.

W. B. E.—Gelatino-chloride prints stand quite as good a chance as platinum or bromide prints, only as the matt-surfaces are far more artistic, they frequently add to the existent charms of a picture and improve it. We shall be glad to welcome you.

J. TATHAM.—The error was a slip.

V. R. I.—(1) The stains upon No. 1 print look as though caused by contact with metal, on No. 2 by dirty pyro-stained dishes, on No. 3 by some acid having been dropped on the print. (2) The tone is all right, and No. 1 is insufficiently printed; 2 and 3 suffer from halation, and using too much bromide and pyro in developer. (3) No, there is nothing to choose between the two salts; the bicarbonate is a little stronger, and in powder that is why it is used. (4) 8 gr. pyro is too much; 4 grs. is certainly enough for one half-plate.

JUNUS.—Provided your negative is not stained by combination of the uranium with hypo, you can remove the intensification by soaking the negative in carbonate of soda or ammonium solution 1:20 for ten minutes, then washing well in water.

ARTIUM MAGISTER.—You give us no idea of what you want the shutter for, nor about what speed. Tylar's window-blind shutter is a cheap efficient one, or a blind shutter such as the Kershaw or Thornton-Pickard is more elaborate and very effective.

H. A. BRAWN.—Never take portraits in the sun; if you do, the result will be patches of white in the print such as you now complain of.

BLACK.—We never have published an article on this particular method, but as a rule black velvet or deep ruby red cloth is used, and a vignetter inside the camera. We hope to be able to induce the worker you name to give us a little article on this subject. We will, if you like, send you down a sketch of th vignetter.

HIPPED.—The P number we have found to be 50.

J. DENEOW.—Fallowfield, 146, Charing Cross Road, sells prepared ferrotype plates, and will send you the formula for developing them. Any of the rapid plates—Fry, Elliott's Studio, Paget xxxxx, Edwards' isochromatic, etc.—are all suitable for home portraiture.

G. H. HOBSON.—Your letter has been put in the waste-paper basket.

PLATES.—We have received two half-plates, but can find no letter about them.

J. G. S. MACKENZIE.—We gave notice in our issue for June 24th of our intention to exclude such queries. In giving the formulae in French weights, the idea was to bring the whole up to some easily-measurable quantity. The weights are not intended to be the exact equivalents, but of the same value compared to the total amount of solution. Many thanks for your suggestions; another edition is now on the road, and your suggestions come in very opportunely. (1) Probably because it has been more recommended by the plate-makers than any other preservative, and also partly because it was one of the first recommended. (2) We have not tried the paper since the new start, but we have heard similar statements from others. Try the Eastman chloride paper.

(3) Yes, the German papers are quite as easy to work, and possess distinct features of their own. (4) Strictly speaking it is not right, but in certain cases it is allowable to use it, disregarding the dwarfing or distortion. (5) Are you not over-exposing the rapid plates? in our hands they have always proved to be one of the easiest to obtain density with. Can you send us up a negative or two? (6) The idea of not using sulphite with ammonia is that the plates are more liable to give green fog than when sulphite is used with a fixed alkali. (7) All methylated spirit now contains wood naphtha. Pure spirits of wine will take its place. (8) Any local working optician ought to make you one for 5s.; it is not on the market.

BATTY.—Wrench was a well-known optician in the sixties, and had a very good name.

G. TOWER.—The prints would be admissible as landscape.

S. G.—(1) The brown spots are silver stains; there is

no absolutely safe way of removing them. Try sulphocyanide of ammonia 20 gr., ferricyanide of potash 2 gr., water 1 oz. (2) The negative preserver is satisfactory. (3) Obtain some slow transparency plates, such as Edwards', Fry, Thomas, or Mawson's, and expose to gaslight behind your negative in contact; then develop with ferrous oxalate; you will then have transparencies.

W. R. P.—(1) Almost any red or orange dye would do. The best plan is to varnish the back of the negative with matt-varnish, and then work up with a crayon and stump; almost any of the aniline dyes will serve, which could be obtained from any dealer. (2) The gelatine mountant has decomposed, and should be thrown away. (3) You cannot claim the negative, and 5s. is a very reasonable price for it.

KEILETT—Obtain some waterproof backing paper as sold by Wheeler and Co. or Percy Lund; mount this with good starch, paste on the back of the prints whilst on the glass, and then, when dry and stripped, mount in the usual way.

F. M. EMERY.—We commence next week or the week after some articles which will tell you all you want to know.

E. MURTON.—(1) Out of focus and over-printed. (2) We should think this was fogged on right hand side, otherwise good. (3) A very difficult subject to take; the negative is too hard, hence the chalky houses. (4) Good, but would be improved by shading the distance in printing. (5) Over-printed. (6) Over-exposed. (7) The distance wants shading; camera was not upright. Not quite up to competition standard. The blocked-up distance is due to using too much reducing agent in the developer. The streaks in No. 5 are due to the brush. Where you get blank white patches in the prints, cover the back of the negative with red matt varnish, and then scrape the varnish off the dense parts so as to allow them to print more than the rest.

W. A. WATTS.—The matter of your letter must stand over till our return from the Convention.

J. WILLIAMSON.—Letter next week.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence.

Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word: compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the **AMATEUR PHOTOGRAPHER**, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, **AMATEUR PHOTOGRAPHER**, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques or Postal Orders, made payable to **Hazell, Watson, and Viney, Ltd.**, 1, Creed Lane, London, E.C.

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number, the name and address being registered, and letters forwarded for a fee of 3d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the EDITOR, **AMATEUR PHOTOGRAPHER**, 1, Creed Lane, London, E.C., who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

**Cameras, etc.**—5 by 4 camera, three double slides, and Eastman's rollholder, £2 15s. Seen before 7 p.m., Saturday 2.—Bradford, 13, Marine Street, Jamaica Road, S.E.

Marion's half-plate camera, long extension, four mahogany backs, in cases, fitted finder, 4 guineas; Watson's 30s. Cyclist's tripod, sliding legs, sell 17s. 6d.; pneumatic shutter, 4s.; light-tight box for 24 negatives, 2s. See after 7 p.m.—Edwards, 86, Chesterton Road, Notting Hill, W.

**Hand-Cameras, etc.**—Fallowfield's Facile hand-camera (4 guineas), including two boxes of plates, 4½ by 3½, almost new, camera carries 12 plates, price 3 guineas, bargain.—Herbert, 13, Hughtend Grove, Garston, Liverpool.

**Lenses, etc.**—Lancaster's quarter Le Merveilleux, two double slides and case, complete, 21s.—E. Swift, Shaftesbury Drive, Grassendale, Liverpool.

Taylor and Hobson's quarter detective lens, iris diaphragm, Kershaw's shutter, cheap, 00s.; good hand-

camera and three best double dark slides, 20s.—H. Cooke, 3, Weekday Cross, Nottingham.

London Stereoscopic Company's quarter-plate R.R., Waterhouse diaphragms, excellent condition, cost 2½ guineas. What offers?—No. 314, office of this paper, 1, Creed Lane, E.C.

Portable symmetrical lens (Optimus 10 by 8), price £3 10s., a splendid instrument; 12 by 10 burnisher (new), 35s., cost £3; also whole-plate ditto, 22s.—Emery, 24, South Street, Baker Street.

Optimus 7 by 5 R.R. lens, almost new, 32s. 6d.—No. 316, office of this paper, 1, Creed Lane, E.C.

Dallmeyer 6 by 5 R.R., cost £5 10s., for 60s.; Newman's shutter to fit, 15s. extra, cost 30s.; Ross' portable symmetrical, 5 in. focus, cost 70s., for 40s.; Optimus Euryscope 7 by 5, cost 94s. 6d., for £2 10s.—H. H. Parly, 9, Cradock Street, Swansea.

**H.S.**—Optimus magazine, 12 quarter plates, Eury-scope lens, fitted by Taylor and Hobson with Shew's instantaneous shutter, two barrels to lens, two sets stops, two sets carriers, two finders, level, polished mahogany walking-stick stand, price 5 guineas.—D. S. Bird, Cheam, Surrey.

Half-plate mahogany camera, leather bellows, brass-bound, by Ross, London, three double metal slides (Tylar's), Thornton-Pickard instantaneous time shutter, fit lens 2½ in. diameter, two-fold ash tripod, leather case with lock, hold camera, etc., set in perfect condition, price £10, camera alone cost £11; approval; deposit.—Apply, Barton, Morrison, Elgin, Scotland.

Camera, lens, and stand, Watson's Premier 10 by 8, for sale, quite new.—No. 315, office of this paper, 1, Creed Lane, E.C.

For sale, half-plate double extension camera with raising front, swing and reversing back, and four double dark slides in case, and three-fold tripod, 60s., or with R.R. lens, Waterhouse stops, and Funnell's shutter, time and instantaneous, £5 10s.—G. Goose, 31, St. Maur Road, Fulham.

**Sundries.**—Vols. No. 8, 9, 10, 11, 12, 13, 14, 15 of the **AMATEUR PHOTOGRAPHER**, in excellent condition, only one copy missing from whole volumes, price 2s. each.—Benest, 52, King's Square, Goswell Road, E.C.

Exchange silver, centre seconds, patent chronograph stop watch; want well fitted hand-camera.—Amateur, 88, Washington Road, Sheffield.

**AMATEUR PHOTOGRAPHER**, 61 numbers, not soiled, 4s. Offers?—Bridges, Carmelite Terrace, Lynn.

Lancaster's 10 by 8 1891 Instantograph camera and one double dark slide, all latest improvements, cost £5 5s., price £3 17s. 6d.; quarter wide-angle lens, by Ross, London (No. 14,064), with two adaptors and flange, only £1 12s. 6d.; Lancaster's whole-plate Instantograph shutter, 5s.; lantern lens (no flange), 5s.; 10 by 8 air-tight glass dipping bath and dipper, best mahogany case, screw top, cost 27s., for 14s. 6d.; 10 by 8 glass bath, slightly cracked, cost 27s., for 10s.; diamond detective, 3½ by 2½, cost 90s., for 18s., good as new.—Hutchinson, Mercer Row, Louth.

200 numbers **AMATEUR PHOTOGRAPHER**, 100 "Photography," 100 miscellaneous photographic. Reasonable offer accepted.—Field, Montana, Blackheath, S.E.

## WANTED.

**Background.**—Wanted at once, few backgrounds, and accessories.—Bramley, Photo, Hucknall Torkard, Notts.

**Hand-Cameras, etc.**—Wanted, Kodak, No. 3 Junior, or No. 4 folding, or Shew's Eclipse camera; approval.—A. Huddart, Eskdale, Carnforth.

**Negatives.**—Stereoscopic negatives wanted, good subjects. State lowest price to A. P. Mann, Stereoscopic Slide Publisher, 48, Elgin Avenue, London.

**Sets.**—Wanted, half-plate set; will give in exchange quarter brass-bound Instanto 1891, three double slides, lens, shutter, legs, and sling case, with cash to value, or sell quarter set for 55s.—Micklewood, St. Michael's Terrace, Plymouth.

Wanted, Lancaster's half plate International set, good condition; must be cheap for cash.—F. Bailey, 17, St. John's Lane, Canterbury.

**Sundries.**—Wanted, **AMATEUR PHOTOGRAPHER**, posted regularly weekly. State lowest price to Cope-man, Henstridge.

**Bargains in Hand Cameras.**—Shew's Eclipse hand-camera, half-plate, latest pattern, fitted, rapid rectilinear, lens, rotating stops, four slides, with carriers for either films or plates, the whole fitted in leather, covered carrying case, a real bargain, take £7 10s. Half-plate Rover, by Lancaster, quite new, iris stops, all same shutter finder, leather case, take £3 17s. 6d. Stereoscopic Company's Graphic hand-camera, fitted, Stereoscopic Company's black band rapid rectilinear, iris stops, lever focussing, blind shutter, changing box, covered leather, £4 17s. 6d. as new; Clement and Gilmer hand-camera, covered black leather, automatic changing bag, twelve plates, good lens, iris stops, two finders, carries twelve quarter-plates, as new, take 75s.; Optimus magazine hand-camera, carries twenty-three, quarter-plates, fitted Euryscope rapid rectilinear lens, instantaneous roller blind shutter, two finders, as new, take £5 15s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 17s. 6d.; and another, 15s.; Lurzo hand-camera, by Robinson, Regent Street,

quarter-plate rapid rectilinear lens, time, and instantaneous shutter, finder, and leather case, carries 100 films, £4 10s.; No. 1 Kodak, as new, rapid rectilinear lens, instantaneous shutter fitted, 50 films, covered leather, in case, £2 17s. 6d.; Adams' Ideal, rapid leather, new few weeks since, very latest pattern, rapid rectilinear lens, carries twelve quarter-plates, two finders, etc., £5 17s. 6d.; Griffiths 4-plate magazine hand-camera, carries twelve plates, changing bag, good lens, finder, etc., 22s. 6d.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, 32s. 6d.; Ariel hand-camera, Shew's eclipse pattern, leather bellows, quarter-plate, rapid rectilinear lens, rotating stops, Kershaw shutter, three patent Turnbull slides, quite new, take 57s. 6d., all above warranted in very finest order.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Lenses.**—For sale, 15 by 12 Optimus wide-angle symmetrical, rotating stops, 10 in. focus, as new, take £4 15s., cost £9, cheap; 12 by 10 European Triplet, by J. Levi, No. 4 B, a really grand article, suit either professional or amateur for copying and other purposes, quite new, cost £9, take 70s.; 8 by 5 wide-angle lens, fitted rotating stops, f/16, rapid rectilinear, best condition, take 27s.; Ross' whole-plate rapid symmetrical, Waterhouse stops, works f/8, £4 12s. 6d.; whole-plate rapid landscape lens by Tench (this is really same as Dallmeyer No. 8), rotating stops, grand definition, works f/16, will cover 10 by 8, quite new, take 60s., cost more than double; whole-plate True-view lens by Chatterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; whole-plate Suter No. 8, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; cabinet portrait lens, quite new, rack focussing, Waterhouse stops, take 25s., cost 60s.; Taylor's and Hobson's half-plate rapid rectilinear, iris stops, good definition, 45s., quite new. Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d. Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; half-plate Lancaster's Instantograph lens, iris stops and instantaneous shutter, as new, 15s.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, Corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Cameras and Sets.**—Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide half-plate carrier and folding stand, as new, take £5 15s.; Adams' half-plate Challenge camera, wide angle, leather bellows, rising and cross fronts, four double slides in cases, fitted, Optimus rapid rectilinear lens, Waterhouse stops, three-fold stand turn table, top solid, leather case, quite new, take £9 10s. Half-plate Duchess camera, all latest movements, etc., Optimus rapid rectilinear lens, fine definition, Thornton-Pickard shutter (time and instantaneous), two double slides, three-fold stand and case, as new £7 5s. Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; half-plate Underwood's Instanto, warranted as new, reversing back, double slide, rapid rectilinear lens, and folding stand, 75s.; half-plate Instantograph, leather bellows, double extension, Instantograph lens, two double slides and folding stand, best condition, take £2 17s. 6d.; Lancaster's stereoscopic Instantograph, as new, two double slides, 6½ by 3¼ Instantograph lenses, instantaneous shutter and folding stand, take £3 17s. 6d.; quarter-plate Le Meritote set complete, camera, lens, slide and stand, 21s.; quarter-plate 1890 Instantograph, all latest movements, leather bellows, etc., Instantograph lens, shutter, one mahogany and two metal slides, and folding stand, 37s. 6d., all above guaranteed, finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

*It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.*

## OUR VIEWS.

"To hold as 'twere the mirror up to nature."—*Shakespeare*.

The Monday Afternoon "At Home" is discontinued for the present, but will be resumed on Monday, the 5th of September.

OUR VIEWS.—The Photographic Convention—A Photograph of Lightning—The "AMATEUR PHOTOGRAPHER'S Annual" for 1892—Our Supplement.

THE PHOTOGRAPHIC CONVENTION; Exhibit of Apparatus, etc.

LETTER TO THE EDITOR.—The Blister Fiend (Dick Deadeye).

ARTICLES.—Elementary Photography (Hodges)—Holiday in Norway—A Universal Hand-Camera (Bruno)—The Theory of Development (Armstrong)—Relative Exposure for Varying Proportions of Image to the Original (Debenham)—The Rapid Hydroquinone Developer (Lainer).

APPARATUS.—The Bynoe Printing Frame (Beck)—Wormald's Cheap Tripod Stand—Stereoscopic Slides (McLellan)—Everybody's Hand-Camera (Birmingham Photographic Materials Company)—Photographic Tabloids (Burroughs, Wellcome and Co.)—Practical Index of Exposure (Wormald)—The Drayton Mill Blotting-Book (Dray and Son).

SOCIETIES' MEETINGS.—Dewsbury—Fairfield—Hackney—Liverpool—Putney.

EDITORIAL DEPARTMENT.—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

### TERMS OF SUBSCRIPTION—

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	" " 6s. 6d.....	" " 13s. 0d.
OUT OF POSTAL UNION ..	" " 7s. 9d.....	" " 15s. 8d.

TRADE ADVERTISEMENTS are received up to Tuesday morning.

PUBLISHING DEPARTMENT.—All letters containing Subscriptions, Orders, Remittances, SALE AND EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZEL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE AND EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

### "Amateur Photographer" Monthly Competition, No. 38.—

"INLAND SCENERY WITH OR WITHOUT FIGURES." Latest day, July 25th.—Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, August 19th.)

THE Photographic Convention has undoubtedly been a very great success. On another page we give the opening ceremony and President's address, which took place on Monday, the 11th inst. Tuesday, the 12th, was devoted to an excursion to Melrose and Dryburgh, about ninety taking part in it.

Wednesday was practically devoted to business in the morning. There was a general meeting, and the venue for next year's Convention was considered. Three invitations had been received, from the Devon and Cornwall Camera Club to visit Plymouth, from Shrewsbury and from the Photographic Society of Ireland to visit Dublin. After considerable discussion, Plymouth was chosen, a proposal that Dublin be chosen being lost.

Votes of thanks to the Lord Provost, to the Board of Manufactures and the Royal Scottish Geographical Society for the use of the hall, and to Mr. Cembrano, the energetic Hon. Secretary, were carried, the latter with resounding cheers. Mr. Cembrano, in his reply, gave statistics as to the numbers, etc., which showed that the Edinburgh Convention was the most successful that had yet been held. Undoubtedly to the Hon. Secretary the warmest thanks are due. He has thrown himself heart and soul into the work, and success has crowned his efforts. After the appointment of the general committee and Council, the members present adjourned to Prince's Street Gardens, close under the Castle, where, on a very well chosen spot, the usual Convention group, in this instance consisting of 130 ladies and gentlemen, was taken by Mr. Aytoun, and a very successful result was obtained.

The afternoon was devoted to the reading of papers, which we shall print *in extenso*. Unfortunately, Messrs. H. P. Robinson and Andrew Pringle were both prevented through illness from being present. Messrs. A. Burchett, Howard Farmer, and F. M. Sutcliffe were also unable to attend. Miss Catherine Weed Barnes, the associate Editor of "The American Amateur Photographer," was exceedingly well received, and her paper listened to with great attention and interest.

On Thursday excursions were arranged for St. Andrews and Dunfermline, under the leadership of Messrs. Cox and Turnbull respectively; both places seem to have well satisfied those attending, the Dunfermline party journeying by rail to Inverkeithing, and walking from there to the Forth Bridge. In the evening more papers were read.

On Friday excursions were made to Dalmeny and Cramond Bridge, Roslin and Hawthornden by coach from Waverley Steps, and in the evening the dinner and smoking.

concert took place at the Waterloo Hotel, nearly one hundred sitting down, including a very good sprinkling of ladies, an innovation which was warmly commended by the members.

After the dinner the usual loyal toasts were given, and then that of the Convention by the President, Mr. George Davison, which was replied to by Messrs. Cembrano and Barclay, the general and local Secretaries. Mr. W. H. Walker proposed "The Ladies," which was responded to by Miss C. Weed Barnes. "The Press," proposed by Mr. Lang, was responded to by Messrs. Traill Taylor, Sturmeay, Welford, Ward, and Wall. The toast of "The President" was proposed by Mr. C. H. Bothamley, and duly replied to. Mr. H. Smith proposed "Our Absent Friends," and Dr. C. L. Mitchell, of Philadelphia, U.S.A., returned thanks for the gratifying reception recorded to the American representatives.

During the evening songs were given by Mrs. Mason and Mrs. Warneuke, Miss Barnes reciting an original poem on "Milan Cathedral," and Messrs. Mason, Scott, Cox, Bridge, Crook, Rettie, Werner, Welford, Cranston still further adding to the harmony of the evening, which was wound up at a late hour by the singing of "Auld Lang Syne." On Saturday morning there was merely a formal council meeting, and the most successful Convention meeting yet held was broken up by the return of the numerous members to their various locales.

ONE of our readers, Mr. Ed. Rice, has kindly sent us a photograph of a flash of lightning of rather curious form, which we reproduce. It is interesting to note how the flash has divided, seemingly lessening in width at each dividing point, and it will be noticed also that the flash did not descend to the earth, but ran along the sky, and in the silver print from which the block has been made it is possible to see that, in some cases, it passes behind little bits of clouds, and in one place on the lower line to the right a fine flash has split off and again joined the main flash further on.

OUR publishers are now ready to deliver copies of the "AMATEUR PHOTOGRAPHER'S Annual for 1892," the publication of which has unfortunately been delayed through unforeseen circumstances.

We believe that this annual is the best that has yet been issued devoted to photography, in the matter of illustrations, which include one bromide print, one silver print, five collotypes, and about one hundred process blocks.

The literary matter contains "A Summary of Photographic Progress during 1891," "Illustrated Notes on Form and Composition in Landscape Photography," in which the author, the Rev. F. C. Lambert, has pointed out the faults and methods of improving the composition of certain pictures, which will be found a valuable practical art lesson. In "Architectural Photography" the Rev. T. Perkins gives clear instructions for following out this useful and interesting branch of photography, and the article is illustrated by four collotypes from negatives by the author.

In the summer our "Queries and Answers" columns are inundated with requests for and details of information as to where to go and what to photograph, and in the "Holiday Guide for Photographers" we have endeavoured to collect together a mass of information which will be invaluable to our readers. Information of about 500

different photographic haunts is given, including distance from town, the railway route, dealers and dark rooms, and also in most cases valuable information as to the best spots to photograph. We think this section of the "Annual" will be found of inestimable value, and, as it is illustrated most copiously, it will be also a guide as to the composition of pictures. A section is also devoted to the leading novelties in apparatus, which will also be found useful.

The work forms a handsome volume of nearly 600 pages, and being neatly bound in scarlet cloth is not likely to suffer from constant usage, as with paper-covered books.

WE regret that in consequence of our absence from town whilst attending the Convention, we shall not issue the Illustrated Supplement till next week, the 29th inst., but we venture to think our readers will not object to the waiting, as it will give us far more time to see justice to the pictures in printing.

## Letters to the Editor.

### THE BLISTER FIEND.

SIR,—I have been much troubled with this complaint. I have tried a few places in which they said the paper would not blister.

TAKEN ON JULY 5, 1892, BY E. RICE.

I found the methylated advice very good; in fact, when used, blisters did not appear. I put the prints in a bath of the spirit before fixing, one at a time, and let them remain in each five or ten minutes before taking out, and let each one thoroughly saturate. I then fixed in the usual way, and the paper that had previously been all for blistering was thoroughly cured. The only drawback seemed to be that the spirit took all the stiffness or goodness out of the paper, but to a great extent this came back again on drying. Salt and ammonia were of no use in stopping the fiend! However, I was induced to try another brand of paper, as I did not take kindly to the methylated spirit remedy, and I wrote to the Scottish Sensitised Paper Company, 57, Hope Street, Glasgow, for a shilling sample. I used the usual formulae with it, and found at last satisfactory results free from blisters, and toning with a beautiful purple colour. I was so pleased with the results that I have procured more from the same Company. In sending this information, if I have done anything towards abating this complaint I shall feel I have been of some little use to amateurs who have been in the same strait as myself.—Yours, etc.,

DICK DEADEYE.

## The Photographic Convention.

THE seventh annual meeting of the Convention was held last week in Edinburgh, the actual meeting room being the hall of the Royal Scottish Geographical Society, Queen Street, kindly lent free by the Board of Manufactures. Though other Conventions have been successful it was universally acknowledged that the Edinburgh meeting would eclipse them all, not only in number but also from the fact of a very large proportion of ladies present.

At 7 p.m. on Monday, the 11th inst., the hall was crowded, and the Lord Provost, supported by numerous civic dignitaries and the officers of the Convention, took his stand on the dais, and Mr. L. Blanc briefly introduced the Lord Provost, and spoke of the honour done to Edinburgh in being selected by the Convention.

The Lord Provost expressed the great pleasure it gave him in welcoming to the city of Edinburgh the Photographic Convention of the United Kingdom, who were exponents of the present state of photographic art. To realise the advancement photography had made since its early days, they had merely to compare the first daguerreotypes with the exquisite productions of the present day. Some had said that photography could not be associated with the fine arts, but the sun was merely a brush by which a man produced his individuality on his photographic works. Referring to the possibility of producing photographs in the colours of nature, he said it was, even more than photography itself, in its infancy; something had been done, and much might be anticipated. There was no doubt as to what it was doing for science. Astronomical science in particular had been greatly indebted to photography, which had demonstrated the existence of suns and systems invisible to the eye even when aided by the telescope. However, their great pleasure would at present be in seeing photography developed as a fine art. He hoped the Convention would have a very happy time while in Edinburgh, and that the weather would prove auspicious for their projected excursions.

Mr. C. H. Bothamley, in the absence of Mr. W. Bedford through indisposition, thanked the Provost on behalf of the Council for the welcome accorded. Whilst they had been fortunate in the places hitherto chosen, he was sure Edinburgh would be equal to them. As it was the President's province to chronicle the improvements in photography, he would content himself with briefly introducing Mr. Geo. Davison, who, although not the gentleman first selected for that office—Mr. H. P. Robinson, on whom the first choice had fallen, being unable through physical infirmity to accept the Presidency—was held in the very highest esteem amongst photographers, not only as a successful worker, but also for his tact and organisation, qualities he possessed in the very highest degree.

Mr. George Davison, who was received with cordial applause, then gave his address as follows:—

I wish, at the outset of our Edinburgh meeting, to give expression to the lively feelings of interest and sociability with which, I am sure, photographers from all parts have come together to confer and fraternise with their comrades of the northern capital.

Of all the conventions, conferences, congresses, and association meetings which are organised to further the interests of various pursuits, none, I think, can be held to be more appropriate to a summer gathering than a reunion of photographers, whose practice naturally leads them at this season of the year so greatly to outdoor occupation; and at no place in the provinces more than Edinburgh, in itself, its surroundings and its photographers, could there be greater certainty of finding stimulus to artistic practice as well as to scientific inquiry in photography. It seems natural and right that photographers should gather in this sociable way each summer, and particularly happy that they should meet in this beautiful city on an occasion when the heads of the organisation have signified in some sort their recognition of the artistic applications of photography by seeking as president our veteran in the art, Mr. H. P. Robinson, and, failing him, one younger, though not less enthusiastic in devotion to the same branch of camera craft. I have faith, then, that the cordiality and sociability characteristic of the camera will, in conjunction with a sympathetic seeking of the beautiful, be specially marked and remembered in connection with this Edinburgh meeting. Notwithstanding the jealousies and quarrels of specialists, which, indeed, may be regarded as significant of superabundant life and energy, there is certainly a sympathy felt wherever a fellow-worker in photography is met. As the use of the camera becomes more and more universal, such sympathy and unity may become less and less noticeable, but in the early history of any pursuit they are an important factor in progress. It is to be hoped that, despite all passing dissensions and personal differences, photographers will always foster the fraternal spirit prominently witnessed in the very idea and existence of the Convention we are now holding.

On looking around at the general position in which photography

is found to-day, I think there is room for satisfaction at the activity and promise displayed. Photography is extending its borders in every direction. In its capacity as handmaid to other sciences and arts, and in its industrial applications, there seems no limit to its utility. Directly, as a profession, or as a pastime, it also grows apace, and I can see little justification for the prophecy we have all heard that the rage for photography would die out as did that for rinking. So far from this being the prospect, photography, with its attendant incitement to the study of light, optics, and chemistry, its cultivation of the powers of observation, general and artistic, and as an indispensable means of record for travellers, has become a necessary concomitant of our advancing civilisation, and seems likely to extend its influence until the camera will occupy a place in every educated household as naturally as the piano and even, in some sort, will be made part of the ordinary education of every boy and girl.

Having said so much in regard to the general outlook, I propose to direct my remarks chiefly to one particular aspect of our progress in photography, namely, the art aspect. It was, indeed, with some doubt and diffidence concerning my topic that I accepted the honour of the Presidency of this year's Convention. In being called on to address the large body of practical and scientific men who impart life and usefulness to this organisation, and, through them, to speak to many photographers as well as the general public, I felt I could say nothing in technical criticism of recent purely scientific advances or inventions in photography which would not have been already better summarised and explained. Apart from a general and popular interest in these improvements, such observations as I have been able to give have been, as you know, directed in a different channel, and it is only as these new developments and discoveries have seemed to me to have a bearing upon pictorial work in photography that they have had any great attraction for me, and that I feel able to discuss them. I shall have, therefore to ask for the patience of those who, by some misfortune in their constitution, hold that mere picture-making is a waste of time, and that it is only in its applications to science and the industries that photography should be seriously regarded. Despite the expression of such views, I deem it unnecessary, at this date, to argue that photography is capable of direct artistic application. Such a position you will generally agree, it would be absurd to gainsay. The exact extent or limitation of the powers of photography in this direction is a very different matter. New means and new methods are being constantly introduced, and it will be best to leave it to time and steady effort to prove its capacity and its limits. I welcome, however, this public opportunity of renewing, to the fullest reasonable extent, the art claims of photography, and of inciting all photographers with artistic tendencies and ambition to inquire into and apply to their purpose every new means, method, instruments, or practice, which science can devise, or which their insight and needs call for and suggest.

I think the state of photographic art at the present time is not without encouragement. It has passed through several phases. It started under the friendly auspices of recognised artists, many of whom seemed to expect that it would do, automatically, more than, even with training, it can be made to do; and later, when their disappointment came, it has suffered from an equally unreasonable excess of opposition from some of a certain class of painters, who, while using it, find it possible, at the same time, to roundly abuse it. Early in its history it discovered one or two who understood and mastered some of its powers, and that work remains a marvel of excellence and strength or a triumph of skill in the handicraft.

To-day interest in its development has been freshly roused by keen discussions as to the distinctive qualities of photography, as to the naturalness of certain methods of focussing, as to tone relations, and as to the qualities yielded by the several printing processes in respect of gradation, surface, quality, and colour. I am of opinion that there has been a great advance made, and that the improvement is still going on. It has been stated that the imparting of superior artistic qualities by the suppression of definition was an old idea, and had been ably and exhaustively discussed in London societies thirty years ago, and that the present movement would probably die out as that died out. I do not think this is a safe forecast. I have not thought it worth while to inquire how ably and exhaustively the matter was thrashed out, but I cannot but think it must have been a one-sided view, as far as the photographers in those societies were concerned, for none of them seem to have had the courage of their opinion to practically and adequately illustrate the broader treatment. It is a very curious circumstance that almost the only valuable artistic survivals from that period are in that particular broad focussing. I refer to Mrs. Cameron's powerful and original pictures, which, to day, are universally admired. However, the present movement is not confined to matters of focussing, nor is it due to any individual, or clique of individuals. The general result of it is happy, in that many photographers have been set thinking and working, and more general and special recognition of

the artistic powers of photography has resulted. Only a few days ago a well-known and very popular painter, referring to certain pictures of the class indicated, said to me that he wished he had one or two representative photographs of the kind for his painter friends to see. They were quite unacquainted, he said, with what was being done, and could be done, in this direction, by photography. Painters could not be induced to visit photographic exhibitions, and were prejudiced by the great mass of ordinary photographs which are displayed in the shops. In the same way Mr. Seymour Haden recognised in these photographs the power to seize on beautiful impressions of a subject, and secure what he termed painter-like qualities.

Do not let it be thought that I wish to arouse afresh any bitter controversy as to the relative merits of different kinds of focussing. Impressions differ, and truth and naturalness in these matters are as various and defensible as the likes and dislikes of different people. We shall do well to keep each of us to the truth that seems the best truth to us, after fully and fairly trying all; or, better still, to cultivate that frame of mind which leaves us free to apply any and every principle or plan as it seems best to suit the purpose in hand. I frequently see photographs which would be considered quite sharp, possessing most charming qualities, though generally in the direction of the beauties of the miniature or the somewhat rigid steel engraving. My own preference is greatly in the other direction. Photographs in various degrees and qualities of diffused and differentiated focus may still be deficient in some essential qualities, but the general tendency of this treatment seems to me to leave open greater possibilities of securing the broad character of a subject, what has been referred to as painter-like qualities. I do not think it necessary to discuss in detail how far, or if at all, the beauty lies in the use of a rough-paper medium or in diffused treatment; I simply indicate that their tendency appears to me to be towards affording greater scope for, and likelihood of, securing the general sentiment, as opposed to a more detailed and decorative interest in the resulting work. It may be that this is merely a fashion, conventionality in art; but, if so, the conventionality is there, good or bad, and it is certain that results by these methods best please those who have had artistic training. It is merely an accident—or a natural consequence, if you will—that these pictures are open to be mistaken, and are mistaken, for sepia drawings. In the same way, sharp and glossy photographs may be called imitations of the still older miniature paintings. No one method has a monopoly of all qualities. The artist in miniatures may have as much perception as the impressionist of broader treatment, although it be a different perception. It will be best, perhaps, to consult and abide by our individual preferences in this matter, as also in that of the much-discussed question of composition, where there may be a preference for the fascinating excellence and subtle combination and direction of line and arrangement of light and dark in spaces, or, on the other hand, for the charm of naturalness of effect and the spirit and character of natural scenes or incidents. The attitudes in the cultivation of these two excellences are somewhat opposed to each other, and the man who marries the two in his expression by painting, and without seeming effort, is the genius we may all conspire to worship.

Here I am reminded of the very interesting discussion as to the separation or relation of science and art, which has recently gained some prominence in our societies and journals, and which seems particularly prompted in connexion with photography. The photographer, especially in a new and growing art, and one in which the tools are less simple and direct than in other more definitely handicraft arts, cannot afford to disregard any new weapon which seems to promise aid to his purpose, whether given by science or prompted by the practical necessities of other workers. At the same time, any interest in science or mechanical work, apart from its application to the one pictorial end purely, cannot fail to vitiate the character of the result from an artistic standpoint. The argument is the same as in the painter's art. There is a large tract in the domain of the artist altogether uninvaded by science, as the term is reasonably understood. A great painter may be practically scienceless; his knowledge of appearances may have been gained in an unscientific way, and better so. He sees, he knows; and the process of his observation and knowledge, and of the expression of his message, is at present past finding out. At the same time, it cannot be said that artists are better without science. It is, indeed, to their advantage to make use of every new fact and discovery; and art in the present day seems to require more and more erudition. An absolute scientific falsity is a distinct blemish. The case cited by Captain Abney of the painter who painted a rainbow inside out in respect of the sequence of colours, and then charged twenty guineas for setting it right, is a good, if apocryphal, instance. Mr. H. P. Robinson pointed out that the picture was not less beautiful in one way than in the other, and this is true as far as ninety-nine out of a hundred observers would be concerned; but, in so far as the painting is for all, and that spectrum analysts have probably still some slight

interest in pictorial art, their feelings ought to be considered, and such a defect should certainly have been wiped out, and without charge. A picture may be great and beautiful in its truth or its fancy, in spite of many technical and scientific ignorances, but it would be better still without such blots. A great natural genius may, straight out of the heart of nature, draw beauties in a way that a student of the very latest theories of light relations, perspective, focus, colour, would miss altogether, but still it is of the utmost importance that all this knowledge should become part of the equipment of every new man who feels a mission to move our susceptibilities by graphic art. It stands out clear that for the average man the two paths of science and art lie apart or diverge. The man who devotes himself to science and to purely scientific habits and research thereby cuts himself off, more or less, from the development of his artistic perception and knowledge. The sciences of colour, and light, and biology, and the knowledge of kindred sciences necessary to master these, form a life work for any one man, as do also the science of appearances and the cultivation of the powers of expression and skill in selection and arrangement. Each man has his natural bent. Nature does not yet exhaust herself in one great stroke by reconciling in any one existence or work the seeming contradictions of science and art.

Adverting to somewhat more practical matters in connection with recent photographic affairs and events, it is hardly possible to pass by altogether, on such an occasion as this, the temporary excitement which has been roused concerning a Photographic Institute, and other attempts to organise concerted action in the form of photographic surveys, geological, local, archaeological. Some good work has been instituted in the latter directions by scientific associations, and by a few energetic provincial photographic societies, but it seems to be a matter of some difficulty to secure anything like combined action amongst photographers. Such an end can only be attained by associating those interested in the several applications of photography. The great schemes for an Institute of Photography, in which students could be adequately taught and trained in photo-mechanical processes, in industrial applications of photography, and in methods of scientific inquiry, seem unfortunately to have now been lost and forgotten, notwithstanding the admirable outline suggested in the paper read by Professor Meldola. If such a college or technical institute is to have promising initiation, the first steps must evidently be dissociated from any one association or clique, and even from those who might be called on for some support, namely, those directly interested in photography commercially. Speaking as a practical organiser, I think that with a purely scientific and practical body urgently called together, in the first instance, by such a committee as Captain Abney, Professor Meldola, and Sir Henry Trueman Wood, and chiefly composed of certain representatives from the leading scientific societies—astronomical, chemical, engineering, meteorological, and the like—a dignity would be imparted to the movement which would possibly secure wealthy, energetic, and influential support.

The initiation of a nationally useful enterprise of this kind might be held to come within the scope of the work of the Society of Arts, seeing that the movement is so intimately associated with progress in science and in art, and aims to fill a gap which constitutes a national misfortune. Under the auspices of an independent and powerful organisation the undertaking should surely meet with success, and there would no longer be felt the frequent necessity for going abroad to find practical craftsmen in photo-mechanical processes. The question as to whether photographic art should be included specially as a study in the curriculum of such a college seems to be a matter of divided opinion. For myself I hold there is very great scope for teaching in this direction, and such an institution could not be considered complete without due provision for instruction in portrait and landscape picture-making. At the same time a complete photographic college with laboratories would be a great task to contemplate at the outset, and the first, and most probably self-paying, department which suggests itself is instruction in photo-mechanical processes. Probably one of the best introductions to the initiation of an Institute movement would be the holding of a fully representative photographic exhibition, in which the many applications possible to photography should be practically illustrated in separate scientific departments, and the art section placed separately. In face of a cry for a technical school of instruction in the industrial, scientific, and artistic applications of photography, it is a matter for some surprise that such an exhibition, which would be the best practical evidence of the opening and scope for a teaching Institute, has not been arranged. I believe it would prove a natural and easy step to what is desired.

Suggestions have also been revived for the foundation of some kind of State record office, and the value of permanent photographs of many subjects, objects, and individuals in the future would, if judiciously classified, certainly be found to be as great as that of most printed and written documents, some of which, indeed, are priceless. But there seems to be great difficulty in making and

centralising such collections, and each division of applied photography is left to make its own disjointed collections. There is a gallery, or portfolio, of photographic portraits of prominent men and women in course of accumulation, due to the initiative of the Amateur Photographic Association, and deposited, I believe, at South Kensington Museum. Such permanent photographs, more particularly if free from much, or any, retouching, should, in time, help to prove the need for a still more extended work in the same direction.

The subject of photographic exhibitions naturally finds a place in my remarks. I think the tendency in that respect must, from an artistic standpoint, be held to be satisfactory. The more it is regarded, the more, I am sure, it will be seen that any system of classifying artists' pictures, and judging and giving medals to them, is out of place and objectionable. The public interest which is now felt in all the leading exhibitions is quite sufficient to form an inducement in those cases for exhibiting, and the smaller local exhibitions may be left for the moment out of consideration. The best argument to be adduced in support of this view is the success which has attended the International Exhibition at Vienna, the English Exhibition at Brussels, and the practical repetition of this latter at Lincoln, in all of which, by selection and invitation, a better average of excellence and a far greater credit to photography have been the result. In this connexion it will be remembered it has been a frequent custom to divide the art section of photography exhibits into amateur and professional classes. For this, I think, there can be absolutely no defence if the exhibition has any pretensions whatever to be called an art exhibition. In art there can be no division of amateur and professional in the common acceptance of the terms. For the requirements of defensive trade union, or for club and general distinction, the division may be deemed advisable or not, but in art there is only quality—the good and the bad—whether the pictures be for sale or not.

Referring briefly to some recent inventions or introductions which appear to have some relation to art photography, we come first upon the great excitement of photography in natural colours. There is nothing practical as yet in this respect to deal with; but as two of our foremost photographers—one in science, the other in art—have, in the interest of artistic appearances, deprecated any such discovery, may we not ask why this should be so? Should we not rather welcome, with the keenest enthusiasm, a power of colour, confident of ability to avoid the commonplace and the mechanical, and of success in applying it to direct artistic purpose?

In lenses there have been the tele-photographic combinations, introduced here by Mr. Dallmeyer, with which magnified pictures of distant objects, little short of marvellous, are produced, and which, in some cases, it is quite conceivable would be applicable to an artistic purpose. Quite recently the concentric lens of Messrs. Ross has been described and introduced, and this would appear to give the power of diffusion of definition, accompanied by rapidity. How the quality of the definition compares with that of the patient pinhole, I cannot say; but, as far as I have any experience, I have not yet seen any quality of definition so pleasing as that yielded in diffraction photographs, and I would strongly urge the more extended use of pinhole photography. In connexion with lenses for artistic purposes this opportunity may also be taken of drawing attention again to the use of large single lenses opened out to an intensity of  $f/4$  or wider, as employed by Mr. Lyonel Clark for portraiture of large heads. The excellent results obtained by him certainly justify and call for a more general practice of the method. Under the head of control by means of lenses, I may refer in general terms to a method of local control, which, I understand, Mr. Van der Weyde has devised, and of which he will shortly give a full description. By this method the relative proportions of features in portraits or of objects in other pictures can be altered at will. The relative increase or diminution of parts can be carried to any extent, and it is evident that the process will be possible of both artistic and grotesque application.

Passing on one step, there has been considerable attention devoted to aids to exposure, particularly in Messrs. Hurter and Driffield's system, on the ground that only by exactly correct exposure can the true relative gradation of a subject be secured. Speaking merely from practical experience, in landscape work, however, the differences in general quality and character in prints from negatives which have received various degrees of over-exposure are not appreciable, provided that a thickly coated sensitive plate be used, and the development be arrested at the right time. The great practical result of Messrs. Hurter and Driffield's admirable work seems to me to be the simplification of development for all photographers. In regard to sensitive plates for the artist photographer, the tendency must, doubtless, be in the direction of thickly coated and orthochromatised plates used with screens. In regard to thick plates, what, as far as I know, is a new departure has been made by the introduction of a plate with emulsions of varying rapidities coated one upon the other, thereby giving great latitude in over-exposure, and greatly obviating halation, one of the most insidious and often unsuspected causes of trouble to the photographer.

It is, perhaps, in respect of new and modified printing processes that the artist photographer of to-day can be most congratulated. No finer results have ever been produced in colour and general quality than the prints obtained by Mr. Lyonel Clark in working what is now known as his toning process in connection with rough-surfaced papers. There, is, however, the doubt of permanency; and the practical and uncongenial difficulties and uncertainties in the preparation of one's own paper are great objections for the artist, who requires all his attention in other directions. Similar appearances have been obtained in bromide papers, and, with the advantage of permanency in platinotype and carbon, and of the newer methods, the interesting kallitype process might, perhaps, be applied in the same manner. A striking novelty for the artist photographer is the method recently introduced by Mr. Willis of controlling the character and effect of platinotype prints by slow local development with a brush, the development being retarded by preliminary treatment of the print with glycerine. The beauty of some of the results by this means in the hands of a competent painter photographer is very noticeable.

Turning for one moment to photo-mechanical processes, there is not much that is new which would seem to have any special application to artistic photography. The use of photogravure by the general worker has not extended as was anticipated, owing, perhaps, to the practical difficulties to be surmounted, and to the greater satisfaction felt in the production of a single direct print superior in most cases in quality to what the engraving process would yield in numbers. As regards photogravures and other photographic reproductions of artists' pictures and drawings for framing and for journal illustrations, there is still much jealous opposition amongst artists and some hangers-on of the press, who take their cue from these artists as to the quality of such reproductions. No doubt, in the cheaper processes, the general gradations of the picture may be modified if the loss be not obviated by special preparation of the picture; but, at the same time, there is retained in these processes or photogravure reproductions so much more of the character and originality of the artist than is seen in any but the very best wood or other engraving that there can, it seems to me, be no doubt about their becoming more and more used.

I have tried to indicate the state of photographic art among us. I think we may be proud that there is more interest in pictorial photography, and greater advance in this respect in our own than in any other country. It is hardly fair to form a judgment from the harsh, uninteresting, and even grotesque illustrations which are from time to time given in foreign photographic journals, and even those in our own photographic magazines are often very little better; but there are other means of judging of the standpoint in this regard of our brethren in France, Belgium, Austria, Germany, and America. I can only say it would be better, in all cases, if these ill-judged illustrations were omitted.

In conclusion, let me urge that we should not fail in keeping up and standing by the dignity and just claims of what we profess and practise. I think I see in the past a steady and even a rapid progress in art photography, and in the future a hope of still further advancement and of a better position. It is this spirit that has animated me in addressing you, and, instead of having to appeal for tolerance, I feel I may make bold to claim a fervour of agreement from you, a union against all enemies, and a combining to overcome all obstacles to our progress.

We shall be sustaining the true and fitting spirit of this Convention if we can all continue to advance together in the science, the art, and the good fellowship of our common object—photography.

Mr. Crooke, of Edinburgh, proposed a vote of thanks to the President for his excellent address, and this was seconded by Mr. W. Lang, jun., of Glasgow.

In acknowledging the vote, the President said that they had to congratulate themselves on having present some transatlantic visitors, viz., Miss Catherine Weed Barnes, of New York, and Dr. Mitchell, of Philadelphia. Mr. F. E. Ives and Dr. Liesegang were unfortunately prevented from attending.

Mr. J. Traill Taylor proposed a vote of thanks to the retiring President (Mr. Wm. Bedford), who was unfortunately confined to his room through ill-health. Mr. Cembrano seconded this, and it was carried unanimously.

Refreshments were served in an adjoining room, and then a lantern entertainment was provided in the large hall.

#### THE EXHIBIT OF APPARATUS, ETC., AT THE CONVENTION.

The first thing that struck one on entering the hall was the exhibits of bromide print enlargements. At the end of the hall, at the back of the dais, was a fine show of untouched enlargements, by MESSRS. MORGAN AND KIDD, from negatives of F. C. Turner, all of very fine quality. This firm also shows some large enlargements from negatives by Van der Weyde. All the pictures were hung

against a dark-green drapery background, and one and all were of first-class technique and good pictures.

THE EASTMAN PHOTOGRAPHIC MATERIALS COMPANY also show some very fine work, enlargements of extreme beauty and enormous size, some from negatives by Lafayette, and others done at the Paris house. A very striking exhibit of this firm also are some enlargements from negatives of a large variety of dogs by T. Fall. Naturally, considerable interest was evinced by visitors in the specimens of printing on the new Eastman chloride printing-out papers, which gained universal commendation for the beauty of tones. Demonstrations of toning the paper were also given at intervals. A brave show of the new Kodaks was also made on a stand, together with chloride prints and lantern slides from Kodak negatives.

ELLIOTT AND SON, of BARNET, show two fine enlargements in carbon, one a breaking wave, the other a collie taken by Thomas Fall.

MR. T. SCOTT, of LEADERVALE PHOTO WORKS, EDINBURGH, has two moonlight carbon enlargements; and MESSRS. A. AND W. SCOTT, of WEST SAVILE TERRACE, EDINBURGH, also show several frames of carbon enlargements.

J. PATRICK AND SON, 52, CORNISTON ROAD, EDINBURGH, show two bromide enlargements, and several fine prints of Scotch views.

THE FRY MANUFACTURING COMPANY, of 5, CHANDOS STREET, LONDON, W., exhibit the enlargement of Mr. J. C. Golding's picture, "Going out to Sea," on rough bromide paper toned with uranium, which attracted a good deal of attention.

F. K. HURMAN and Co., of 2, ST. NICHOLAS BUILDINGS, NEW-CASTLE-ON-TYNE, have on show a very fine 15 by 12 studio camera and stand, the St. Klaas; the camera is of excellent construction, and possesses several new features, the back and front both moving with rack and pinions and independent of one another. A special arrangement prevents sagging of the bellows. Three dark slides are provided, one large one with Venetian roller slide for taking direct pictures either way, and two smaller ones with repeating fittings for C D V and cabinets. The stand possesses several features of novel construction, and is extremely rigid.

THOS. J. WALLS, of 47, LOTHIAN STREET, EDINBURGH, shows several novelties, and a hand-camera with dark slides of simple and efficient make. On the same stand is a Champion paper cutter, which takes paper the full size, and has a sliding gauge marked in inches and a cutting guide, shown by WOOD, of KALMAZOO, MICH., U.S.A.

MR. C. BAKER, of 244, HIGH HOLBORN, LONDON, shows a very fine optical lantern with microscope attachment, and a water trough.

MR. A. C. SMITH, of 255, ALBERT ROAD, PECKHAM, LONDON, has a novelty in hand-cameras, the Slide Lock, which carries the plates in sheaths in a magazine in the top, which is provided with a slit through which the plates drop on pressure of a projecting pin. A single lens working at  $f/10$  is provided, and a shutter actuated by a lever.

J. F. SHEW AND Co., of 87, NEWMAN STREET, OXFORD STREET, LONDON, exhibit several forms of their well-known hand-camera, the Eclipse, and also their new magazine hand-camera, The Repeatograph, which is extremely ingenious, the plates being changed and shutter set by moving a lever from side to side. On this stand also are to be seen the Daisy metal printing frame, which is very light and small, and has no possibility of warping, the whole being of metal, except the back; and Beales' "Nonactinine," a deep ruby liquid for stopping-out skies, defects, etc., and strengthening weak negatives, or local work.

THE SCOTCH AND IRISH OXYGEN CO., LTD., ROSEHILL WORKS, POLMADIE, GLASGOW, show cylinders for compressed gases, and Brier's patent metallic regulators, both complete and in section, also a new fine adjustment valve. Three cylinders are also shown, which were subjected to very severe tests whilst fully charged with gas; one, 6 ft. 6 in. long, charged with oxygen at 1,800 lbs. per square inch, was dropped 35 ft. four times across an iron block; another was treated in the same way, and then  $6\frac{1}{4}$  cwt. dropped from a height of 35 feet on to it. A smaller cylinder 2 ft. 9 in. long, filled with liquefied carbonic acid, at a pressure of 750 lbs. per square inch, was dropped sideways and endways on to the block, and then flattened by  $6\frac{1}{4}$  cwt. being dropped on to it, but, beyond flattening and bending, the cylinders well withstood the tests.

A. H. BAIRD, of 15, LOTHIAN STREET, EDINBURGH, makes a special show of the Lothian universal plummet, a giant model of this demonstrating its action; the Lothian hand-camera; combined lantern slide masks and binders, etc.; the Todd-Forret magnesium flash-lamp, and Mr. F. Dundas Todd's picture of "The Village Smithy," which won our Silver Medal, taken by the same. A magnificent photo-micrographic camera 10 ft. long, specially made for the Photographic Company of St. Bernard's Row, Edinburgh, is also on view.

W. WRAY, of LAUREL VILLA, NORTH HILL, HIGHGATE, LONDON,

has a case full of lenses, both in brass and aluminium fittings, of all sorts and varieties, including the Detective and casket lenses.

WM. HUME, of 1, LOTHIAN STREET, EDINBURGH, makes a specially good show of his useful and well-known Cantilever enlarging lanterns, the latest and cheaper form, The Nimrod, being prominent. Mr. Hume also shows the Thornton-Pickard shutter and other little appliances.

W. WATSON AND SONS, of HIGH HOLBORN, LONDON, rely upon their Acme cameras and cyclist stand, and have a very good exhibit of the same. The Watson and Vanneck hand-cameras were also *en evidence*, and work done with the same.

R. W. GREEF AND Co., of 29, MINCING LANE, LONDON, make a good display of Rodinal, eikonogen, and a new fixing salt which they are introducing, which has several advantages, and of which we shall shortly have more to say. Negatives, prints, and lantern slides developed with Rodinal are also shown, whilst just above this stall are some fine specimens of printing on Scholzig's sensitised paper.

GEO. HOUGHTON AND SONS, of HIGH HOLBORN, LONDON, have several interesting novelties, amongst them their new revolving table for printing vignettes, etc., which is actuated by clockwork, and will carry one or many frames. A new interchangeable leaf album is also here, the leaves fitting on two pins, and being held down by a cross-bar. The Shuttle hand-camera also attracted a good deal of attention; but the greatest novelty is a new instrument for viewing prints, which is called the "photo-chroscope." In appearance this looks somewhat like a retouching desk, and cut-out photographs are laid on the slope, with a suitable cloud picture, and by means of side cords the illumination of the same can be changed at will. Some of the night scenes treated in this way are extremely effective.

## Elementary Photography.

BY JOHN A. HODGES.

### CHAPTER XXV.

#### PLATES, PAPERS, ETC., AND THEIR PREPARATION.

Technical Knowledge Desirable—"Photography with Emulsions"—Dry Plates—How Prepared—The Emulsion—Sensitiveness—Digestion—Washing—Coating the Plates—The Operation Described—Drying and Packing—Deleterious Influences—A Word for the Plate-makers—Bromide Paper: How Made—Silver Paper—Albumenising—Sensitising—Preservatives—How to Keep Albumenised Paper—Celluloid Films—Drawbacks and Advantages.

ALTHOUGH it is quite possible to become a skilful photographer, and yet know little or nothing of the materials which are used in the production of the pictures, it cannot be doubted but that even a slight knowledge of the nature and preparation of the plates and papers and other materials in common use can be otherwise than helpful in times of difficulty, I therefore make an apology for adding this chapter to the pages of "Elementary Photography." I can, however, only treat the subject in the briefest possible manner, and I would refer the reader who desires to extend his knowledge to Abney's "Photography with Emulsions," a book which all photographers should possess.

Astonishing as the statement may seem, there are not a few amateurs who, though able to produce very passable photographs, are totally unacquainted with the nature and mode of preparation of the sensitive plates and other materials which they are accustomed to use in the production of their pictures, but as I do not wish this reproach to apply to those whom this book may initiate into the mysteries of the art, I trust my readers will peruse and not pass by this chapter.

The modern dry plate consists of a sheet of glass evenly coated with a sensitive preparation technically termed an "emulsion." This emulsion consists of bromide of silver, mechanically suspended in a very fine state of division, in a solution of gelatine. The emulsion is prepared by dissolving either bromide of potassium or bromide of ammonium in water, with a small quantity of gelatine. A second solution is made by dissolving nitrate of silver in water. Then, in

Its History, Processes, Apparatus, and Materials: comprising Working Details of all the more important Methods.

By A. BROTHERS, F.R.A.S.

GENERAL CONTENTS:—Part I. Historical Sketch; Chemistry of Photography; Optics of Photography; Light in Photography.—Part  
II. Processes.—Part III. Apparatus.—Part IV. Materials used in Photography.—Part V. Applications of Photography; Practical Hints.

\* The Volume is fully illustrated with Twenty-four Full-page Plates by the different processes described, and contains  
many Tables and Woodcuts in the Text.

"A most comprehensive volume. . . . The PRACTICAL HINTS are of great value."—British Journal of Photography.

"Certainly the FINEST ILLUSTRATED HANDBOOK to photography ever published. . . . SHOULD BE ON THE REFERENCE SHELVES OF EVERY PHOTO SOCIETY."—  
Amateur Photographer.

A FULL PROSPECTUS ON APPLICATION.

London: CHARLES GRIFFIN & CO., Ltd., Exeter Street, Strand.

the dark-room, the silver solution is added to the bromide solution slowly, and with vigorous stirring, when the bromine combines with the silver, and forms bromide of silver, which is the sensitive silver salt. It is very essential that the combination should take place slowly, in order that the silver bromide may be produced in a fine, and not a coarse condition, the former being found to give better results than the latter. This is effected commercially by special mixing apparatus, not unlike a huge churn in appearance. An emulsion so prepared would be too slow for general purposes, and the vessel containing it is placed in a hot-water apparatus, in which the emulsion is kept at a high temperature, or even boiled, for a certain time, until the required sensitiveness is attained. When this stage is reached, the emulsion is allowed to cool and the necessary quantity of gelatine added, for were the full amount used in the first place and during the boiling process, it would lose its setting properties, and the plates, when coated, would not dry. Before the emulsion is in a fit state for coating the plates, it has to be "washed," in order to remove the soluble nitrate of potassium, which is formed at the same time as the insoluble bromide of silver. The emulsion is forced through coarse canvas, a silver grating, or broken up by other mechanical means into small particles. These are enclosed in a suitable apparatus, and a continuous current of water passed through until all the soluble salts are dissolved. The emulsion is then drained and remelted, when it is ready for coating.

Formerly plates were coated by hand, but now all commercial plates are coated by machinery. An endless band carries the glass plates underneath a vessel containing the liquid emulsion, by which they receive a thin and even coating of emulsion; the endless band, which is kept travelling at a uniform rate of speed, takes the coated plates onward through a short metal tunnel, the outside of which is packed with ice; this causes the films to set, and upon their emerging from the far end, an assistant lifts them off, and stacks them in racks, which, when full, are removed to the drying chambers or darkened rooms through which a continuous current of air is passed, generally by mechanical means. When dry, the plates are, in all good factories, properly tested, and, if approved, passed on to the packers, who do them up in the boxes which are so familiar to photographers.

It will be seen from this brief account that the preparation of an emulsion is by no means an easy matter, and if the reader only knew the infinite care and trouble which the leading plate manufacturers take in order that they may be in a position to offer their customers a reliable article, they would pause before attributing their failures to their plates rather than to themselves. Some plates possess better keeping qualities than others, but all are liable to deteriorate if exposed to damp or the fumes of gas, therefore these adverse conditions should always be avoided.

Perhaps gelatino-bromide paper ranks in importance next to the dry plate. It is, as its name indicates, paper coated with gelatine emulsion. The emulsion is prepared in the same manner as that used for plates, the only difference being that it is far less rapid, and less gelatine is employed. Indeed, in some papers, particularly those with a rough surface, the quantity is reduced to a minimum.

Ordinary albumenised silver printing paper undergoes two processes in the course of its preparation. Large sheets of specially-made paper, usually of German manufacture, are first albumenised by floating on large dishes containing albumen, to which a certain proportion of some soluble chloride has been added. After flotation the sheets are removed, and dried in a warm room. So prepared, the

paper will keep indefinitely. This part of the process is very often done in Germany, from which country the bulk of the albumenised paper used in England is exported. The paper is made sensitive to light by floating it on a silver bath containing about 60 grains of nitrate of silver to the ounce of water. After floating for three minutes, the sheets are removed, and hung up to dry in a warm room. Paper so prepared will not keep, and must be used fresh. The method by which the manufacturers confer keeping qualities upon their sensitised papers is a trade secret, but the result may be achieved by floating the paper on a bath of citric acid, or by keeping the paper between folds of blotting-paper, which have been soaked in a saturated solution of carbonate of soda, and dried. The secret of preserving ready-sensitised paper for a long period is to keep the air from it, and the best way of doing this is to store it under pressure, either in a large printing frame or in a press. If it be first wrapped up in some old or discoloured sensitised paper it will be found to keep almost indefinitely.

Glass has until recently been almost exclusively adopted as a support for the sensitive material, but recent improvements in the manufacture of celluloid have led to the adoption of the latter material for the same purpose, and celluloid films, as they are called, are now largely used by amateurs. Their chief advantage lies in the great reduction of weight and bulk, and the absolute immunity from any danger of breakage. The chief and perhaps only drawback to their use is the difficulty experienced in getting them to lie flat in the dark-slide during exposure. This is greatly obviated by the use of a carrier, several patterns of which are now procurable, one of the best and lightest being England's cardboard carrier. The manipulation of the ordinary thick films does not in any way differ from that of ordinary plates, but with the very thin rollable films, a little care is necessary in order to keep them beneath the surface of the developer. If a dish with a plain bottom be used and wetted, and the film then placed in it, the capillary attraction will be sufficient to cause it to adhere, and will prevent it from rising to the surface of the developer.

**Photography in Colours.**—M. G. Lippmann, who has been continuing his researches, has communicated further results, which appear in the *Comptes Rendus* for April 25th:—"In the first communication which I had the honour to make to the Academy on this subject, I stated that the sensitive films that I then employed failed in sensitiveness and isochromatism, and that these defects were the chief obstacle to the general application of the method that I had suggested. Since then I have succeeded in improving the sensitive film, and, although much still remains to be done, the new results are sufficiently encouraging to permit me to place them before the Academy. On the albumen-bromide of silver films rendered orthochromatic by azalin and cyanin I have obtained very brilliant photographs of spectra. All the colours appear at once—even the red—without the interposition of coloured screens, and after an exposure varying from five to thirty seconds. On two of these *cliches* it has been remarked that the colours seen by transmission are very plainly complementary to those that are seen by reflection. The theory shows that the complex colours that adorn natural objects ought to be photographed just the same as the simple colours of a spectrum. There was no necessity to verify the fact experimentally. The four *cliches* that I have the honour of submitting to the Academy represent faithfully some objects sufficiently diverse—a stained-glass window of four colours, red, green, blue, yellow; a group of draperies; a plate of oranges, surmounted by a red poppy; a many-coloured parrot. These showed that the shape is represented simultaneously with the colours. The draperies and the bird required from five to ten minutes' exposure to the electric light or the sun. The other objects were obtained after many hours of exposure to a diffused light. The green of the foliage, the grey of the stone of a building, are perfectly produced on another *cliche*; the blue of the sky, on the contrary, was represented as indigo. It remains, then, to perfect the orthochromatism of the plate, and to increase considerably its sensibility."

## A Holiday in Norway.

PHOTOGRAPHY AMONG THE FJORDS.

(Continued from page 40.)

### V.—GUDVANGEN, STALHEIM, AND BERGEN.

FROM Balholm to Gudvangen, our next stopping place, was but a Sabbath day's journey. Therefore the captain steamed past the entrance to the Nærø Fjord, at the bottom of which Gudvangen lies, and took us first to explore the Lyster Fjord, an arm of the Sogne Fjord, opening out from it to the northward. It was Sunday morning, and, as on the sea, so here a Sabbath stillness reigned. Not even a ripple broke the oily placidity of the deep dark waters through which the great ship slowly moved. The long shining furrows that streamed from her prow as she slid smoothly on soon subsided, and all was peace behind us and before. Mirrored in this natural glass lay the hilly sides of the fjord, and the vivid verdure that swept up their lower slopes from the water's edge to where the rocks and trees held sway.

one, springing in one magnificent leap of 600 feet from the ledge where it first forms itself, and then wasting its slender stream in shadowy mist before it reaches the bottom of the cliff 2,000 feet below. But far above even the source of the Kilfos the mighty crests of the hills tower, rising in gigantic succession, one after the other, all the way to Stalheim, a distance of seven English miles. So narrow is the valley, so stupendous are the hills, here black and gaunt from the shock of the tempests of ages, there brodered with moss and lichen, and broken by falling ridges of dark dwarf firs, and everywhere

"overstream'd and silvery-streak'd

With many a rivulet high against the sun,"

that one is awed into silence. Nature seems so great and man so little. And in the silence come strange fancies, till one can almost hear—

"Sweet and far, from cliff and scar,

The horns of Elfland faintly blowing."

It is not hard to understand the origin of Scandinavian mythology when one has been up the Nærodal. Along the bottom of this cleft ravine, and fed by many falls from far up

STALHEIM AND THE NÆRODAL.

Most of the fjords through which we passed were perfectly desolate and uninhabited, the rocks often plunging sheer down into the water, and making a landing impossible. But in the Lyster Fjord it was not so. Nestling amidst the emerald meadows on either hand, here clustered into pretty little hamlets, and there standing separate and alone, were scores of warm and red-roofed houses with fronts of glowing white.

#### THROUGH THE NÆRODAL.

The afternoon brought us back into the Nærø Fjord to Gudvangen. Thus far the country had been delightfully free from all signs of that degeneration which, in sorrow be it said, too often follows the footsteps of the tourist. The Norwegians are still an unsophisticated folk, generally speaking. But the popularity of their country as a holiday resort is increasing so rapidly that one fears for them. Gudvangen showed us that such fears are not groundless. It is, and it deserves to be, "a show place," because it is the entrance to the magnificent Nærodal. But here for the first time the little children who opened the gates for passing vehicles asked for money, and the *skjælgut* showed an inclination to haggle for more than his proper fare. Still nothing, not even all the beggars in Killarney, nor all the "cabbies" in London, could spoil the grandeur of the Nærodal. To begin with, as one leaves the steamer and lands at Gudvangen, the Kilfos, "the highest perpendicular waterfall in the world," bursts upon

the hills, whirls a mountain stream, glimmering through the trees, dashing over the rocks in foam and fury, and sometimes falling into quiet backwaters, cool and crystal clear. In many places the road, which winds along by the side of this stream, is worn away by some new freshet that has broken from the snows above, and becomes nothing more than the bed of a mountain torrent. At last the dome-like peak of *Jordalsnuten*, one of the most striking of the Nærodal mountains, comes into sight, and beyond it, far up in the hills, the sun flashes on the Stalheim Hotel. Ere that is reached, however, two splendid falls are to be seen, the Sivlefos and the Stalheimsfos, the former of which, as it thunders down its rocky channel, sends up great drifting clouds of misty spray, that ascend like the smoke of a great fire and completely deceive the traveller till he is within a few yards of it.

#### AT STALHEIM.

Past these, one comes to the *Stalheims-kleven*, a wonderful zigzag road that leads up to the hotel, climbing many hundreds of feet in nearly a score of serpentine windings, and finally giving a glorious view of the valley just traversed. The majestic peaks tower high above one still, but their lower cliffs and falling ridges jagged with pines lie interwoven before one down a vista of seven long miles, the silver stream threading the valley beneath, and the Kilfos, small and dim, making its wonderful leap in the far distance. The Stalheim Hotel is justly praised as one of the

finest in Norway. Its magnificent entrance-hall and dining-room are incomparable, and every window commands a charming view. Here, for the first time too, we saw the national costume worn by the girls who waited at dinner. Very pretty was the effect produced by the vivid colours and the lavish ornament on neck and wrist. From Stalheim some of the passengers went on to Vossevangen, by way of Opheim, Vinje, and Tvinden, repeating their experiences of grandeur and beauty in the Nærødal, and finally reaching Fleischer's Hotel close by the marge of the Vangs Lake. There they slept, and on the morrow took the train to Bergen along a track hewn out of the solid rock almost the whole of the way. There are fifty or sixty tunnels to be traversed during the journey, but one is rewarded by the enchantment of the scenes that burst upon one after emerging from the darkness, by the glimmer of the lakes and the glory of the hills. But there were others who returned from Stalheim through the Nærødal to Gudvangen, and thence sailed out of the Sogne Fjord, and through the island-studded sea around the coast to Bergen. For them, too, there were beauties by the way. It was enough even to lean over the vessel's side and idly watch the wash that swirled astern in crisp white eddies, and broke into creamy feathery flakes of foam dancing for a moment on the crest of the wave and then dying into the dark-blue sea. It was enough to lie and bask in the

lent music was given in the evening, the *Domkirken* or Cathedral, the museum, and the summit of *Floifjellet*, the first part of which is ascended by means of the *Dramveien* (literally "dram road") built out of the profit on the sale of spirits, of which Bergen has the monopoly. From this and the six other hills by which Bergen is surrounded—like Rome and its seven hills—the views that may be obtained of the busy town jutting out into the sea, and of the protecting islands that break the force of the outer ocean, are delightful; while inland one catches charming glimpses of the country and the stately *Folgefond* glacier and of many a hill and lake across the Bjorne and Hardanger Fjords. The *Triangelen*, or fish market quay, close to the junction of *Strandgaden* and *Torvet*, is especially worth a visit, and the *jæger* in the harbour, a peculiar kind of sailing boat, adds to the quaintness of the scene. As for the people themselves, they are uniformly most civil and courteous, casual passers-by invariably lifting their hats. Whenever a shop is entered, too, the same courteous custom is observed as on the Continent. English is very generally spoken, or at least sufficiently well to enable "the intelligent foreigner," who in this case happens to be the Englishman himself, to make himself understood and to procure whatever he may want. The music in the *Nygaards Parken* in the evening was especially good, and the fine grounds of the park, skilfully laid out, seemed to become the fashionable promenade of Bergen for the occasion. But for the language and a certain lack of finish and style of dress, the crowd might well have passed for English. Bergen, it may be said, or more properly a suburb of Bergen, is the home of Grieg, whose compositions are so characteristic of his native land. He is not without honour in his own country, for we heard that his silver wedding had been celebrated with great rejoicings two days before we arrived.

(To be continued.)

## A Universal Hand-Camera.

BY MAJOR BRUNO.

(Continued from page 22.)

THE various parts of the box, and the interior arrangements being now ready, the next step is to fit them together, and to add the parts necessary to furnish a central swing to the camera back. Prepare two pieces of  $\frac{1}{4}$ -inch stuff of the dimensions given in fig. 14, viz.,  $5\frac{1}{2}$  inch, by 1 inch. In the centre of each let in a brass plate B,  $\frac{1}{2}$  inch by  $\frac{1}{4}$  inch, of thin sheet-brass, and drill a hole right through both brass and wood. This hole must be accurately in the centre of S S. The holes should be of such a size that they will take the shanks of the screws which pass through them into the sides of the camera back (see B and D, fig. 11), just an easy fit. The object, of course, is that when the two upright fillets S S (fig. 14) are fixed in the box, the camera back swings centrally between them, pivotted at B in each of the uprights. At this stage it must be clearly understood that a set-screw passes through the left upright S (i.e., that on the left of box looking towards the front) at B; and entering the bush B (fig. 11), can be clamped or released through the side door. But on the right side the upright is screwed to the inner side of the box, and no set-screw is required here; merely a screw inserted in the bush D (fig. 11), with the head removed, so that the shank serves as a pivot for that side of the "back."

It will be seen that a plate of sheet-brass, P, with a quadrant-shaped slot, extending through the wood, is let

THE SEVEN SISTERS—GEIRANGER FJORD. (See page 22)

sun on the forecastle deck, and watch the purple islands as they passed, and to sink into reverie under the spell of the glowing light and the charm of the cerulean sea; and at last to see in the snowy spray of the breaking waves the milk-white hands of Ocean's fairy daughters beckoning to the great sea halls in the depths below.

### IN AND AROUND BERGEN.

So we came to Bergen, perhaps the most picturesque town, as it is one of the largest in Norway. We landed in the *Pudde Fjorden*, and very soon discovered the *Torvet* or central market square, the quaint quays and wharves opening out of the *Strandgaden* to the *Vaagen*, the old park and the *Nygaards Parken*, where excel-

FIG. 14

into the upright S (fig. 14). This also is only required on the left upright, and is for the set-screw passing into the bush B<sup>2</sup> (fig. 11), which firmly clamps the "back" at any point in the slot when swung on its pivots. A sketch of the arrangement is shown in fig. 15, page 21.

The whole of our material being now complete, commence putting the camera together as follows:—Glue and screw the right side of the box (that is, the side on the right in the direction of the front) to the bottom. Next at a distance of three inches from the back (or focussing) end, firmly screw the right upright S (fig. 14), to the inner right side of the box, the brass pivot-hole outwards of course. Insert the pivot-screw on right of camera back, and taking the left upright S, insert the pivot set-screw, and having the camera back so swung that it will work freely, mark out the position of this upright. It must be exactly opposite the upright already screwed to the inner side, so that the camera back is quite square with the ends of the outer box.

Having marked out its position on the bottom and top of the case, proceed to cut mortice holes for its reception, removing half the thickness only of the wood forming the top and bottom. Now glue and screw the right side to the top of the box, and fixing the left upright S (fig. 14) in the mortice holes cut for it, glue it in. We have now the right side of the box, fitted to the top and bottom, and the camera back swung between its uprights. It is assumed that the bellows and small front are connected to the camera back, and the next step is to fit the stage M (fig. 13), into its grooves on the sides of the box, and when it is found to travel freely

STAGE FOR FOCUSING, DESCRIBED ON PAGE 21.

to pass the focussing set-screw through the slot F (fig. 5, p. 435) into the bush screwed into the stage M for its reception. The left side of the box (with the hinged door) can next be glued and screwed to the top and bottom, and the case tested for squareness all round. Having got all ship-shape, screw the cleats A A (fig. 6) and the connecting strip C into position, and slide in the focussing panel B. Next, fit the flap of the door in front of the case D (fig. 8, p. 488) in its grooves on left side of box; slide it in, and the door, when closed on its hinges should fit close up to the top, bottom and sides. Slide the focussing screen into its grooves on the right side of the box, screw your lens into its flanges and adjust it to work smoothly in and out of the shutter when the "front" is focussed, and your camera is complete.

Space is provided for three dark slides, or the roll holder, at the back, and the weight should not exceed 4 lbs., with lens and roll-holder in position. If you have not already adjusted and marked the foci of your lenses on the scale, this must be done, and the final finish given to the box itself. If made of well-marked wood, it should be

French polished, or it can be ebonised and left with a dull polish.

It is advisable to use a cover for the case for various obvious reasons, and the best material to make it of is the waterproofed tweed used for lining mackintoshes. It should be procured of a small check or other unobtrusive pattern. Fig. 16 shows the manner in which it can be cut in one piece, and so easily fitted to the box.

S is a slot cut to admit the leather handle we have already screwed to the lid of the box. A is an aperture cut corresponding with the lens aperture in the front of box, and F F are similar apertures for the finder. No bottom is required for the cover, which is slipped over the case and secured with two straps passed round it and through the loops in the handle. Loops to catch on small round-head screws are left at the two ends as shown, and a small hole will be required for the release trigger of the shutter. The cover is also cut to the extent shown by the dotted lines to work the door at side for manipulating the dark-slides, etc. Small catches to hold a card (as a memorandum of exposures) can be screwed to the inside of this door, and the camera is now, in all respects, ready for work. Briefly you have in compact form a hand-camera that will do all a tripod camera will do, and much that it will not. You have the means of making forty-eight consecutive exposures without changing a film, or opening the camera, and with the minimum of trouble. You can equally expose a single plate, no matter what the subject, provided you have lenses of the foci required, together with the means of swinging your camera back to meet the requirements of architectural subjects in a confined space, or to obtain satisfactory sharpness in the various planes.

FIG. 16.

Many suggestions have been made as to the most suitable position in which to hold a hand-camera. The writer prefers to hold it firmly to the right side as high as possible with the thumb of the right hand on the trigger. In this position the finder can be watched with ease. Do not attempt impossible subjects when using your camera for so-called "instantaneous" work. A bright light on the subject (not necessarily sunshine) is essential, and there should be an absence of deep shadow. Do not include rapidly-moving objects at a short range, and above all do not bring photography into evil repute by attempting to take people unawares, and without their permission.

In conclusion, a few words on the development of hand-camera work may be of use. Formulae in shoals have appeared, but the writer prefers the hydroquinone developer, using washing soda and carbonate of potash as the accelerator, not hydrate of soda. If under-exposure is feared, soak your plate for two or three minutes in a weak solution of the alkali. Transfer it to the developing dish and apply the normal developer with very little bromide. This will bring out all detail that particular plate has in its interior economy.

For ordinary exposures in good light the normal developer, applied full strength, should be used, unless the subject possesses strong contrasts, when the pyro or hydroquinone should be reduced. If intended for enlarging, keep the negatives somewhat thin, but for lantern slides or ordinary printing allow them to attain full density. Ordinary

AN UNSOLICITED TESTIMONIAL FROM AN AMATEUR OF

# 22 YEARS' EXPERIENCE.

To Messrs. ELLIOTT & SON,

BARNET, HERTS.

"Dundrennan, Kirkcudbright, N.B.,  
23rd April, 1892.

"DEAR SIR,

I yesterday effectually tested a packet of your **Ordinary Barnet Plates** upon Landscape subjects. I used Drop Shutter on every plate, single Landscape Lens, Stop  $f/16$ , light good, and

**DID NOT MISS A PLATE, ALL GOOD,**  
and without doubt after the full **experience of 22 years** I have no hesitation in placing the **BARNET PLATE** in the very front rank, as a **quick, clean, and easily developed plate of the HIGHEST ORDER.**

"Yours faithfully,

"J. COPLAND."

May be obtained of all leading Dealers, or direct from the Works,

## ELLIOTT & SON, BARNET, HERTS.

plates will be found quick enough for the majority of subjects, but a great advantage in dull weather, or afternoon light, is gained by using isochromatic plates.

Any difficulties in construction which may occur in working out the various parts or fitting them together, will gladly be explained through these columns.

## The Theory of Development

IN RELATION TO THE ESSENTIALLY ELECTROLYTIC CHARACTER OF THE PHENOMENA AND THE NATURE OF THE PHOTOGRAPHIC IMAGE.

By HENRY E. ARMSTRONG, F.R.S.,

Professor of Chemistry in the City and Guilds of London Central Institution.

(Continued from p. 28.)

### II.—NOTE ON REVERSAL: AN ADDENDUM TO PAPER READ AT CAMERA CLUB CONFERENCE, 1892.

"REVERSAL" of the photographic image by continued exposure is not only a phenomenon of great intrinsic interest, but is also of considerable practical importance, on account of the limitation of exposure which its occurrence imposes: it is therefore highly desirable that its exact character should be elucidated. Regarding the phenomena from the point of view advocated in the body of the paper to which this note is an addendum, it appears possible to suggest an explanation somewhat simpler—perhaps more probable—than any previously put forward.

There are apparently two ways in which reversal might arise: either (1) as a consequence of the production of a silver compound which is not developable; or (2) as a consequence of the screening of the latent image from attack by the developer.

Both rehalogenation of the latent image and the formation of an inert oxidation product would come under case 1; but it is highly improbable that the former could ever be complete, or cause more than a partial destruction of the image, for whatever becomes of the halogen which is separated by the action of light from the silver haloid, it may be regarded as certain that a considerable proportion would become fixed—especially that taken up by the gelatine in the case of gelatine plates—and unreturnable to the silver. Complete rehalogenation could only occur in the presence of an excess of some haloid compound which would serve as a source of halogen. Again, although it cannot be said that it is impossible to convert a silver haloid by oxidation under the influence of light into an undevelopable oxy-haloid, there seems, at present, to be no evidence that such an action may occur (*cf.*, however, Mr. Baker's subsequent remarks on this point).

Reversal, therefore, more probably arises from the occurrence of changes such as would be productive of the condition contemplated under case 2. The action of light takes place at the exposed surfaces of the silver haloid in contact with the sensitiser, and the production of the image necessarily involves not only the withdrawal of halogen from the silver haloid but also its fixation by the contiguous sensitiser. The image, therefore, as it increases in intensity during exposure, becomes coated with an ever-growing layer of altered sensitiser, much as the particles of lead peroxide in a lead-sulphuric acid—lead peroxide voltaic cell during action become coated with lead sulphate; and just as in this voltaic cell action takes place less and less readily, and ultimately ceases long before the peroxide is exhausted, owing to the deposition of the non-conducting sulphate on the peroxide, so it appears probable that the coating of altered sensitiser on the surface of the latent image may, if exposure be sufficiently prolonged, acquire such dimensions as to act as a "non-conductor," rendering development impossible, only those parts of the plate responding which have not received what may be termed the *critical exposure*, and which, therefore, are still amenable to the action of the developer.

It may be difficult to apply this explanation to the phenomena of recurrent reversal, but with regard to these the facts on record are at present far too few to permit of their satisfactory discussion.

(To be continued.)

\* Read at the Camera Club Conference.

## Relative Exposures for Varying Proportions of Image to the Original.\*

By W. E. DEBENHAM.

WHEN an enlarged photograph has to be made either from a negative or print, it is commonly understood that the greater the degree of enlargement, the longer will be the exposure required, but I have generally found only the vaguest ideas to exist as to the amount by which such exposure has to be prolonged. Sometimes, indeed, it is assumed that the exposure will be in direct inverse proportion to the area covered, so that a copy of twice the linear dimensions of the original—covering as it does an area of four times the size—would require an exposure of four times that sufficing for a copy of the same size. This calculation, however, omits to recognise an important factor, and leads to serious error; the actual exposure required in the case mentioned (assuming the same lens and stop to be used) being not four times, but two and a quarter times that of a copy of same size; whilst, when we come to high degrees of enlargement, the error would amount to an indication of nearly four times the exposure actually required.

To find the relative exposure, add one to the number of times that the length of the original is contained in the length of the image, and square the sum. This will give the figure found in the third column of the annexed table.

Proportion of image to original (linear).	Distance of image from lens in terms of principal focus.	Proportionate exposures.	Exposures proportioned to that required for copying same size.
$\frac{1}{30}$	1 $\frac{1}{30}$	1.07	.27
$\frac{1}{25}$	1 $\frac{1}{25}$	1.10	.28
$\frac{1}{20}$	1 $\frac{1}{20}$	1.21	.3
$\frac{1}{15}$	1 $\frac{1}{15}$	1.27	.31
$\frac{1}{10}$	1 $\frac{1}{10}$	1.36	.34
$\frac{1}{8}$	1 $\frac{1}{8}$	1.56	.39
$\frac{1}{6}$	1 $\frac{1}{6}$	2.25	.56
$\frac{1}{4}$	1 $\frac{1}{4}$	3.06	.76
1 (same size)	2	4	1
2	3	9	2.25
3	4	16	4
4	5	25	6.25
5	6	36	9
6	7	49	12.25
7	8	64	16
8	9	81	20.25
9	10	100	25
10	11	121	30.25
11	12	144	36
12	13	169	42.25
13	14	196	49
14	15	225	56.25
15	16	256	64
16	17	289	72.25
17	18	324	81
18	19	361	90.25
19	20	400	100
20	21	441	110.25
21	22	484	121
22	23	529	132.25
23	24	576	144
24	25	625	156.25
25	26	676	169
26	27	729	182.25
27	28	784	196
28	29	841	210.25
29	30	900	225
30	31	961	240.25

As examples: Suppose a copy is wanted having twice the linear dimensions of the original. Take the number 2, add 1 to it, and square the sum  $3^2=9$ . Again, if a copy is to be of eight times

\* Read before the Photographic Society of Great Britain.

† With a double lens it is usually sufficient to measure from the position of the diaphragm plate.

the linear dimensions of the original; take the number 8, add 1, and square the sum,  $9^2=81$ . Copies respectively twice and eight times the size (linear) of the original, will thus require relative exposures of 8 and 91, i.e., the latter will require nine times the exposure of the former.

It is convenient to have a practical standard for unity. An image of the same size as the original is a familiar case, and serves as such standard. By dividing the figures in the third column by four, we get at the figures in the last column, which represent the exposure required for varying degrees of enlargement or reduction, compared with the exposure for a copy of the same size.

The table is carried up to enlargements of thirty diameters; that is about the amount required for enlarging a small carte de visite to life size.

The exposures required in reductions do not vary at all to the same extent that they do in enlargements. It has therefore not been thought necessary to fill in the steps between the images of  $\frac{1}{2}$  and  $\frac{1}{3}$ , and between  $\frac{1}{3}$  and  $\frac{1}{4}$  of the size of the original. Beyond  $\frac{1}{4}$  there is scarcely any perceptible difference in the exposure until disturbance comes in from another cause; a considerable distance of illuminated atmosphere (haze or fog) intervening.

The figures in the second column will also serve as a table for distances from the lens to the plate and to the original; all that is necessary being to multiply by the principal focus of the lens in use. In the case of enlargements the figures less than 2 must be multiplied to get the distance from the original to the lens, and the figures greater than 2 for the distance from lens to image. For reductions, the figures less than 2, multiplied by the principal focus of the lens yield the distance from lens to plate; and the figures higher than 2 similarly multiplied give the distance of original from lens.

## The Rapid Hydroquinone Developer.

BY PROF. ALEX. LAINER, VIENNA.

DR. MIETHE has published in the "Photographische Nachrichten" an article about developers, referring to my rapid hydroquinone developer.

As the rapid hydroquinone developers mentioned by me have found many faithful adherents on the continent, it might, perhaps, interest the readers of the *Bulletin* to have a more detailed description of the same.

I have worked out four formulas, of which No. I is the strongest and No. IV the slowest in action.

### SOLUTION A.\*

INGREDIENTS.	FORMULA.			
	I.	II.	III.	IV.
Water .....	1,000	1,000	1,000	1,000
Sulphite of soda, cryst. ....	40	30	35	80
Yellow prussiate of potassium...	120	90	25	30
Hydroquinone .....	10	10	10	12

### SOLUTION B.

Caustic potassa or caustic soda..... 250 grams.  
Water..... 1,000 c.c.

For use, mix for each 13 x 18 cm. plate:

Solution A ..... 60 c.c.  
Solution B ..... 6.12 c.c.

The softness of the negative will increase in proportion to an increased application of Solution B.

Under normal conditions the development is finished in from one to two minutes. Formula I, however, can give a completely developed negative in forty-five seconds, which, at continued development, shows only increased density and will lead to the formation of fog.

The extraordinary reducing power of this cheap developer is surprising; the negatives obtained excel by excellent details in the shadows, and are perfectly clear, provided that the emulsion

plates are good and that the developer has the temperature of well-water (about 12 degrees C.).

The developer, Formula I, has not been surpassed in rapidity and quality to the present day by any other developer, not even by Rodinal, and I may quote the words of an eminent expert, Dr. Just, who writes about the same in Eder's "Year-Book," 1892:

"The excellent results which I obtained with this handsome developer on instantaneous views induced me last summer to test the same on bromide of silver emulsion paper."

Dr. Just writes further: "Lainer's Rapid Hydroquinone Formula No. I, in concentrated condition, as well as diluted with half or an equal volume of water, is quite an excellent and powerful, if not the most powerful, developer for bromide of silver emulsion paper, provided one is in the position to keep the baths at a temperature of 12 to 14 degrees. Nothing was to be observed of a coloring effect; on the contrary, the whites showed such a brilliancy that pictures developed with oxalate looked yellow when compared with the same."

The developer Formula No. IV contains the most sulphite of soda, that is 80 grams per 1,000 c.c. of water. This developer is not of the same highly energetic action, but it possesses a great durability, and to show its utility I might mention that Captain Ritter von Reisinger developed twenty-one dozen dry plates with half a litre of my developer without even one of the plates becoming yellow.

Plates which fog with the before-mentioned developer are finely developed by application of bromide of potassium; the proportionate quantity to be applied is, for instance:

Solution A ..... 60 c.c.  
Solution B ..... 12 "  
Bromide potassium solution, 1:10 ..... 5 to 10 "

In some cases a simple dilution with well-water will act favourably; for instance:

Solution A ..... 30 c.c.  
Solution B ..... 3.5 "  
Water ..... 30 "

There need be no fear that the development is retarded hereby. Exposed plates which, for instance, showed not the slightest trace of a picture with the pyro-soda developer, gave very good negatives, rich in detail, with the rapid hydroquinone developer. An exposure of one-thirtieth of a second with the relative opening of the objective of  $f/30$  gave a fully successful picture in sunlight.

Formula II, besides the proportions for mixture already mentioned, can also be applied with potassa or soda.

Formula II A ..... 60 c.c.  
Potassa solution, 1:2\* ..... 10 "

gives a good negative in two minutes.

Formula II A ..... 60 c.c.  
Soda solution, 1:5† ..... 12 "

gives a clear, not very strong, negative in four minutes

By addition of a little tincture of iodine 1:100, a strong condensation of the highest lights of the negative is prevented; if to 60 A, Formula II and 10 c.c. caustic potass, 1:4, 2 c.c., tincture of iodine 1:100 are added, the gradation in the high lights is influenced, an increased addition of tincture of iodine leads to total flatness and the fixing proceeds much slower. A small addition of tincture of iodine may be of very good use in some cases.

The developed plates are well washed and then fixed in an acid fixing bath.

I generally immerse the plates after superficial washing, in water containing 1 to 2 c.c. muriatic acid per litre, wash again, and then put them in the acid fixing bath.

The clear, acid fixing bath introduced by the writer, which has a clearing and tanning effect, is produced by adding 50 c.c. acid sulphite solution to a litre fixing bath.

The acid sulphite solution is obtained by dissolving 250 grams neutral crystallized sulphite of soda in 1,000 c.c. of water and adding afterwards 50 c.c. concentrated muriatic acid. The acid sulphite solution keeps for a long time in well-corked bottles.‡

The fixing bath can be acidified repeatedly with this acid sulphite solution, but too great an addition should be avoided because the fixing will be retarded. Many kinds of dry plates

\* 100 grams of salts of tartar are dissolved in 200 c.c. of water.

† 100 grams of soda crystals are dissolved in 500 c.c. of water.

‡ The commercial acid sulphite solution also works well.

\* The several ingredients are dissolved by heat.

will fix after from ten to twenty seconds, while others, again require just as many minutes. The application of a second fixing bath is to be well recommended.

By a strict observation of the aforesaid the rapid hydroquinone developers will undoubtedly make many friends. Care should be taken that the temperature of the solutions does not increase more than about 16 degrees C.

Finally, I will give you yet a formula of my mixed concentrated rapid hydroquinone developer.

(A.) Dissolve in 100 c.c. water 30 grams sulphite soda, and then 10 grams hydroquinone by heat; further, 25 grams yellow prussiate of potassium likewise in 100 c.c. water. Both solutions are mixed.

(B.) Dissolve 30 grams caustic potassa or caustic soda in 100 c.c. water. After both solutions have been cooled off they are mixed and poured into small bottles, well corked. The mixture is very stable. I have some from November, 1891.

For use, dilute for rapid development 10 c.c. with 30 c.c. water, for slower development with 60 c.c. water.

The developers should not be thrown away after use; they admit of frequent application, and are of good service for over-exposures, whereas over-exposed plates developed with fresh rapid developer would be lost.—*Anthony's Bulletin*.

## Apparatus.

### THE BYNOE PHOTOGRAPHIC PRINTING FRAME.

Messrs. R. and J. BECK, of 68, Cornhill, E.C., are placing upon the market the above novelty in printing frames.

It is constructed with a metal frame, and is therefore light, strong, and not liable to warp. The negative and paper are placed in the frame by pressure on the small lever, the back having been unclipped and raised as shown in the illustration, and as soon as the negative and paper are in position, the lever is released, a toothed clip firmly grips them, thus preventing any shifting during printing, and at the same time allowing easy examination of the whole print. The back, which is in one piece, gives a very even pressure by means of the spring, which acts on the centre, and is immediately and automatically fastened by a catch. A hole in the lever serves the useful purpose of allowing the frame to be hung up.

With this new frame there are no shadows on the edges of prints, time and space are economised because there is only one pressure spring to release to examine the print, the whole of which is seen at once. The prices are for  $\frac{1}{4}$  plate, 1s.; for  $\frac{1}{2}$  plate, 1s. 9d.; and whole plate, 2s. 6d. The invention is certainly a very useful novelty.

### RICHARDS' PATENT CORNERS.

Mr. Thomas P. Richards, of Westminster Chambers, 3, Victoria Street, S.W., has forwarded us some sample boxes of

his latest novelty, which consist of small gilt corners to affix prints temporarily or permanently to mounts, albums, etc. They are a decided novelty, and will doubtless find many friends.

### WORMALD'S CHEAP TRIPOD STAND.

Mr. A. R. WORMALD, of Sutton, Surrey, has submitted to us a new cheap tripod which he is placing upon the market, and

which not only possesses several novel features, but has the recommendation of cheapness, its price for  $\frac{1}{4}$  and  $\frac{1}{2}$  pl. cameras being only 3s.

As will be seen from the illustration, it is made of wood, and has three wooden rollers into which the legs screw. It is very light, weighing only 1 lb., and is rigid, substantial, and portable.

able, and will find many friends for hand and the ordinary cameras.

### STEREOSCOPIC SLIDES.

Mr. J. W. McLELLAN, of 36, St. Paul's Road, Canonbury, has submitted to us some excellent examples of stereoscopic slides and transparencies. The present revival in stereoscopic work has created a demand for the same, and we are pleased to see the introduction of some new slides from recent negatives; some of the slides represent interior scenes of Westminster Abbey, which are of first-class workmanship and extremely artistic, and the set of zoological studies are well worth seeing. Mr. McLellan is well known as a lantern slide manufacturer.

### EVERYBODY'S HAND CAMERA.

The Birmingham Photographic Materials Company, Ltd., of Gladstone Road, Sparkbrook, Birmingham, have sent us one of these little cameras, which are constructed of ebony wood, and are fitted with achromatic single lens and sliding drop shutter. The dark slide is an extremely ingenious idea, and is especially light, weighing only 2 oz., the camera too weighs only 12 oz. We have actually tested this camera, and find it capable of turning out very good work, although at the low price of 8s. 6d. this might not seem feasible.

### THE PHOTOGRAPHIC "TABLOIDS."

(B. W. & CO.)

Messrs. BURROUGHS, WELLCOME, AND Co., manufacturing chemists, of Snow Hill Buildings, E.C., are introducing a new variety of their well-known tabloids, viz., the photographic, and in these the pyro and accelerator are separately compressed, and they will be found extremely useful not only in ordinary work but for tourists.

### "THE PRACTICAL INDEX OF PHOTOGRAPHIC EXPOSURE."

This useful little companion, compiled by A. R. Wormald, of Sutton, Surrey, has now reached its seventh thousand, and the new edition contains a table of speed numbers, specially compiled from the experience of various workers. A directory of photographic dealers and dark-rooms completes its usefulness.

### THE DRAYTON MILL PHOTOGRAPHIC BLOTTING BOOK.

Messrs. G. W. DRAY AND SON, LTD., of Great St. Thomas Apostle, Cannon Street, E.C., are placing a very convenient blotting book on the market, at the price of 1s. It may be had either plain or corrugated for plain or matt-surface prints. It is fluffless, and absolutely free from hypo and injurious chemicals, and in the convenient form it is issued will be found exceedingly useful.

## Societies' Meetings.

**Dewsbury.**—Monthly meeting on 14th inst., Mr. A. S. Marriott, President, in the chair. The business consisted of examining the Shuttle hand-camera, specially sent by Messrs. Houghton and Son, London. All its working parts was explained and shown by the Secretary, afterwards the members present fully criticised it. Mr. Mitchell showed one of the Talmer pattern, which gave great satisfaction. Sample packets of a new print-out paper by the Eastman Photographic Company were handed round to members. A number of prints by various members were shown. The Secretary stated that he had tried the new paper by the Eastman Company, and used the Ilford toning bath, but found that after squeegeeing to polished glass, they would not strip from it. Mr. H. M. Smith stated at one of the London societies that the sulpho-cyanate bath softens the gelatine. The Secretary said that putting the prints into an alum bath did not prevent them sticking. A number of places were selected as most suitable for society excursions.

**Fairfield.**—The usual monthly meeting was held on Tuesday the 12th inst., Mr. J. L. Mackrell presiding. After three new members had been enrolled, it was announced that the Council, through the President's efforts, had been enabled to secure a presentation platinum-type copy, to each member for the year, of Mr. W. W. Winter's medalled picture "Look, Mamma," which attracted much interest at the late exhibition, catalogued at two and a half guineas a copy. Mr. W. T. Sutton submitted his report *re* new rooms, and it was decided to remove to the High School, Fairfield, in September next, this arrangement enabling the Council to offer more meetings, classes, etc. Mr. Mackrell received a special vote of thanks for his efforts *re* the copy, and afterwards Mr. Chas. Timmins exhibited his 8 by 5 camera, got up almost instantaneously, as a hand-camera. The idea was certainly novel and ingenious, as well as practical. Mr. Timmins was told he had scored well, and was heartily thanked for not keeping his idea dark, as so many do.

**Hackney.**—The usual weekly meeting held on the 12th inst. was conducted by Mr. Beckett, as Chairman, in the absence of Mr. J. O. Grant, and work done on excursion to the Zoological Gardens was shown by Messrs. Sodean, Dean, Nunn, Roder, and the Hon. Sec. Mr. Pollard showed some prints, taken whilst holiday-making, of Tintern Abbey. He was asked if he had permission to photograph there, but he stated he had to pay 2s. 6d. to do so. Mr. Reynolds asked could he use an ordinary reducing solution for Sandell plates when necessary, as he could not manage that quoted. The Chairman preferred Howard Farmer's formula. The ferricyanide would get exhausted after a time. Mr. Sodean said in using too much ferricyanide there would be a loss in the shadows. Mr. Gosling asked if anyone had obtained too much density with Ilford pyro formula. The Chairman observed that if that was so too much pyro was used. The Chairman then called upon Mr. Hill to give a demonstration of the Cresco-Fylma process. Specimens of the process were passed round. The idea was that on immersion (into the above-mentioned solution) of a positive or negative the film would leave the plate and expand into nearly twice the size (demonstrated, with result that equal enlargement took place), and was then transferred to either an opal glass or paper in case of a positive, or glass for negative. The after process was precisely as would be the case of an ordinary print or negative. Mr. Hill stated that hydroquinone was the best developer to use for producing the original negative; alum would act as a repellent, so was not advised; citric acid could be used in pyro. Mr. Barker asked if alkali would affect the stripping. Mr. Hill advised carbonates in preference to hydrates, though ammonia would enlarge perhaps better. Mr. Poulson wanted to know if, in drying, dust was likely to affect the plate, but was informed that it would be perhaps better to wash. Mr. Gosling then gave a demonstration on "Development." He advocated the old theme of one developer, and he preferred pyro soda. He was an "Ilford" man, he said, as he had learnt all he knew from "Scraps," and consequently the plates, etc., he used were of that firm's manufacture. He then developed a negative and lantern plate, but used too deep a light (in the general opinion of those present), which was constructed (for the occasion) out of a biscuit tin.

**Liverpool.**—At the ordinary meeting on the 13th inst., the President (Dr. Webb) in the chair, there was a large attendance of members to hear Mr. W. Haywood's very interesting and instructive remarks upon the subject for the evening, viz., "Comparison of the Rosset Excursion, Exposures and Results," in the course of which he showed upon the blackboard the great differences in the stops used, and the exposures given for each view taken; yet from the negatives and prints that were produced for inspection (showing good results in almost every case) he concluded that careful development had saved many of the plates, and that the plates themselves allowed a deal of latitude in exposure. A hearty vote of thanks was accorded to Mr. W. Haywood. Mr. Yule (who seconded) said these practical demonstrations were of great use, and

that Mr. Haywood's was the best that he had had the pleasure of seeing. During the evening samples of plates, paper, and books were distributed to the members, and gratefully acknowledged, from the following firms, viz.:—The Paget Prize Plate Co., sample packets of their various plates; the Eastman Photographic Materials Co., new gelatino-chloride printing out-paper; the Ilford Co.'s pamphlets on Isochromatic Photography, and Messrs. Mawson and Swan's exposure books. The Ilford Co. also presented a manual for the library. The Eastman Co.'s further presents of two large framed enlargements were hung upon the walls of the club-room, as was a large framed enlargement of views from the Paget Prize Plate Co., and these were suitably acknowledged. In response to a letter from Mr. F. C. Beach, the Editor of the *American Amateur Photographer*, asking the club to sign a petition in favour of free photography at the Chicago Columbian Exposition, it was resolved that the President should sign it, as a protest against one or two firms having a monopoly of photographing the exhibits, etc. The club is now supplied with appliances for developing and demonstrations, and a library for the members' use. The excursions for the month are to Bebington and Storeton on the 21st, and a waggonette drive to Cheshire on the 23rd.

**Putney.**—The ordinary meeting was held on the 4th inst., Rev. L. Macdona in the chair. Messrs. Faulkner and Macdona gave a demonstration in development with Rodinal and pyro-soda, showing how the results of a considerable over or under exposure may be corrected by suitable modifications of the constituent parts of the developer; the demonstration was followed with much interest by the members present. Messrs. Faulkner and Zachariasen exhibited prints on the new "Eastman" chloride emulsion paper, which were greatly admired. Sample packets of the paper, presented by the Eastman Company, were distributed for trial amongst the members. Tylar's "Full-view" printing frame, an improved metal single dark slide, and other novelties were shown and discussed. Four new members were elected. The Society having joined the affiliation scheme of the Photographic Society of Great Britain, Messrs. Macdona, Vice-President, and Zachariasen, joint Hon. Sec., were elected delegates to serve on the Central Committee of the Affiliated Societies. The summer outings, held on alternate Saturdays, to places in the neighbourhood have been very successful; many good negatives have been taken and will no doubt give additional interest to the competition amongst members for the Society's medals. The outings have been particularly instructive to the beginners, who have been able to profit by the kind assistance given them by the more proficient. The next outing will be held on Saturday, July 23rd, at 3 p.m., at Hampton Court.

## SOCIETIES' FIXTURES.

- July 22.—RICHMOND.—Informal Meeting.  
 „ 22.—HOLBORN.—Lantern Night. "A Ramble round Essex, by A. T. Ebsworth. Members, please bring your friends and slides.  
 „ 23.—LIVERPOOL.—Excursion to Chester.  
 „ 23.—PLYMOUTH.—Excursion.  
 „ 23.—PAISLEY.—Excursion to Balloch.  
 „ 23.—OLDHAM.—Ramble to Penistone for Wentworth Castle.  
 „ 23.—BRIGHTON AND SUSSEX.—Excursion to Worthing.  
 „ 23.—CROYDON.—Photographic Ramble.  
 „ 23.—HACKNEY.—"Orthochromatic Work," by W. L. Barker.  
 „ 23.—HACKNEY.—Excursion down the river.  
 „ 23.—BLACKHEATH.—Outing to Hampton Court.  
 „ 23.—STOCKPORT.—Ramble to Worsley.  
 „ 23.—LEYTONSTONE.—Excursion to Barnet.  
 „ 23.—FAIRFIELD.—Excursion to Chester.  
 „ 23.—GORDON COLLEGE.—"Enamelling."  
 „ 25.—HACKNEY.—Excursion to Chislehurst. Visitors welcome.  
 „ 26.—GREAT BRITAIN.—Technical Meeting. "Modern Developers."  
 „ 26.—CLEVELAND.—Toning.  
 „ 26.—E. LONDON.—Ordinary Meeting.  
 „ 26.—HACKNEY.—Discussion on Stereoscopic Photography.  
 „ 27.—LIVERPOOL A.P.A.—Excursion to Shrewsbury.  
 „ 27.—LIVERPOOL CAMERA CLUB.—Exhibition of Prints, and Discussion upon.  
 „ 28.—HOLBORN.—Official Outing to the Southern Counties.  
 „ 28.—STOCKPORT.—Ramble to Worsley.  
 „ 28.—OLDHAM.—Meeting at 7.45 p.m.  
 „ 29.—RICHMOND.—Show of Prints.  
 „ 30.—WARRINGTON.—Excursion to Appleton.  
 „ 30.—OLDHAM.—Ramble to Plumley for Halford Hall.  
 „ 30.—ASHTON-UNDER-LYNE.—Ramble, Hadfield to Crowden.  
 „ 30.—STOCKPORT.—Ramble to Chester.  
 „ 30.—LEYTONSTONE.—Excursion to Greenwich.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### QUERIES.

5760. **Platinotype.**—Is there any license required for the working of platinotype, and is it as simple as other methods, and what the cost and requirements in apparatus; is it different to Lyonel Clark's platinum toning?—**PLATT.**

5761. **Sepiatype.**—How are the sepia photos worked; is there any special method, and what is it?—**PLATT.**

5762. **Hand-Camera.**—Can any reader tell me what is the best focus to have in a hand-camera,  $\frac{1}{4}$  in. to  $\frac{5}{8}$  in. or more?—**FOLIAGE.**

5763. **Whitby.**—Can any friend tell me where to find in Whitby the houses illustrated in the *Queen* of 9th July, best time of day to take them; also where to find Unstead Bridge (see the *Queen*, 9th July) and other good bits?—**C. H. G.**

5764. **Sulpho-Cyanide Toning Bath, Ilford Formula.**—I made up the above about three to four months ago, and toned one whole-plate print, and have not used it since until last week, when the prints went a dirty yellow. Can anyone tell me the cause of same, and how long the bath will keep good?—**AMATEUR.**

5765. **Ferrotypes.**—Will any reader kindly inform me how to take photographs on dry ferrotype plates so as to finish one in a few minutes as the men do that take photographs in the street; what developer should I use, and the method of using it? Are there any glass dry plates that take a positive instead of a negative; if so, where can I obtain them both in glass and metal ferrotype?—**S. H. HOLLOWAY.**

5766. **Sat. Sol. Hypo.**—What is the strength of a saturated solution of hypo—i.e., what quantity of a saturated solution would equal 1 oz. avoirdupois of dry hypo?—**HYPOSTATIC.**

5767. **Distant Photography.**—Can any reader tell me how to photograph objects at a distance through a telescope; also regarding exposure for same?—**VIEW-FINDER.**

5768. **Ostend.**—Will anyone kindly inform me if there are any restrictions to amateur photography in this town, excepting fortifications, of course; also if a hand-camera can be used in the grounds of Kursaal? Any other information will greatly oblige.—**ÆSOP.**

5769. **Studio Builders.**—Will some of your readers, or the Editor of the *AMATEUR PHOTOGRAPHER* kindly give the names and addresses of some studio manufacturers.—**J. SMITH.**

5770. **Stratford-on-Avon.**—Will any reader kindly give me a list of places worth photographing in and just outside Stratford, sufficient for one day's work (say about twelve views)—**TOURIST.**

5771. **Fixed Focus.**—I must apologise to W. A. W. for having forgotten to give the focus of my lens. I meant the point beyond which an 8 in. focus rapid rectilinear lens would always be in focus. Could any one kindly tell me whether I should have to stop the lens very much down that it should give a good depth of focus? Which stop, for instance, and what distance would the lens be from ground-glass? I meant to use this half-plate lens on a quarter-plate hand-camera.—**FRA.**

### QUERIES UNANSWERED.

July 15th.—Nos. 5752, 5753, 5756, 5759.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

### ANSWERS.

5743. **German Work.**—One of the best elementary works is Pizzighelli's "Anleitung zur Photographie," published by Wilhelm Knapp, Halle a/S.—**EDITOR.**

5744. **Blisters.**—The cause of the plates blistering is undoubtedly the caustic soda in the developer. Reduce the amount of caustic and replace with carbonate, and you will probably have less cause of complaint.—**EDITOR.**

5745. **Eastbourne.**—This is a very good centre; Hastings, St. Leonards, Battle Abbey, Hurstmonceux, Pevensey, Rye are all near. A hand-camera is almost a *sine qua non* for beach work.—**EDITOR.**

5749. **Distance.**—In taking open views with a distance which it is desired to obtain, isochromatic plates and a yellow screen are essential. A full exposure should be given if there are any dark objects in the near foreground. In development, commence with 1-10th of a grain of pyro to the ounce, normal bromide and normal accelerator. As soon as the whole of the image is visible but very faintly, throw off developer, and apply one strong in bromide, strong in pyro and accelerator, and allow it to gain density.—**EDITOR.**

5751. **Portsmouth Dockyard.**—Probably a request to the superintendent of the dockyard would obtain all the information you desire.—**EDITOR.**

5754. **Photo-Micrography.**—As the cells of yeast vary from 1-2400th to 1-3000th of an in. in diameter, a

power of 500 diameters would be about the lowest to satisfy H. W.'s requirements. This could be got by using a 1-6th in. objective (as it is not wise to use more than eight times the initial power of the lens unless it be a very good one), but of course a higher power could be used. The light might be sunlight, lime, or paraffin. Any developer will answer, but hydroquinone is a good one for this work. It is hard to give the exposure, as it depends on such varying conditions. The following may help him: I took a good exposed negative of the acropores of Peziza X 700, with a 1-6th Zeiss apochromatic, substage condenser, Ilford Isochromatic plate, screen a weak solution of fluorescein, light lime, mixed jet, in 10 sec.; also with same objective, one of Navicula lyra X 767, with cheap form of Webster condenser N.A. 65, plate Paget xxxxx., lamp one inch wick paraffin, in 8 min. The lens which E. W. uses would probably answer for the work, but if he wants to buy one the apochromatic are the best for photography; if these are too dear, Reichert's lenses usually photograph well, and are cheap.—**J. G. P. VEREKER.**

5755. **Black Varnish.**—I should recommend "Black Art" to use a mixture of very fine lamp-black and gold size. He can mix it to any consistency he finds most satisfactory.—**R. A. R. BENNETT.**

5757. **Bournemouth.**—There is plenty to photograph in Bournemouth and the neighbourhood. The pleasure gardens are well worth half a dozen plates or more. There is Branksome Chine, too, which should not be missed. The shore and steamers will also keep you occupied for a considerable time, and in the neighbourhood there is Christchurch Priory, which is five miles, also Wimborne Minster, ten miles. I should certainly advise "Banty" to bring his camera. Plates can be had here of Mr. W. Jones, chemist, 203, Old Christchurch Road. You might also read the articles which have appeared in the *AMATEUR PHOTOGRAPHER* for Aug. 2nd and 9th, 1889, and Sept. 5th, 1890. These can be had for 3d. each of the Publishers. If "Banty" cares to communicate with me, I shall be pleased to give him any further information (address with Editor).—**FOLIAGE.**

5758. **Washing Prints.**—If "Anxious Beginner" brought in a couple of handfuls of water, he could wash the prints for toning with one handful, and the same water would do for the first washings after the fixing bath, then put them in a dish with some clean water and leave them there five minutes, remove them to a second dish of water, carefully pressing the contaminated water out of them with a roller squeegee, do this a few times and leave them all night in the bath; a short repetition of the same process in the morning will probably leave them free from hyposulphite of soda.—**J. G. P. VEREKER.**

5758. **Washing Prints.**—I do not wonder that you find your present method a little too much of a good thing. Were I similarly situated, the following would be my method: First wash the prints for an hour in changes of water, re-filling the vessel after emptying it, every quarter of an hour; then get a good strong bit of plate glass and another vessel, which fill with water. Take each print separately out of vessel No. 1, squeeze it face downwards onto the glass with a glass roller, wash well, pull it off, and transfer to vessel No. 2. At the end of about a quarter of an hour squeeze them on again and transfer to vessel No. 1, previously re-filled with fresh water. All the hypo ought to be gone now, and you can dry the prints after emptying and refilling once or twice more.—**R. A. R. BENNETT.**

### EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S post if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—**ED. AM. PHOT.**

**IDEA.**—This sounds good, and would cost so little to make that it is worth trying. If successful it would be a big thing.

**PERPLEX.**—(1) The rates of postage per parcel post to Algeria are rather heavy—under 3lb, 1s. 9d., not exceeding 7lbs, 2s. 2d. You would thus be able to have 2 doz. quarter-plates or 1 doz. half-plates only sent for 1s. 9d. or 5 doz. quarter-plates and 2 doz. half-plates for 2s. 2d. Your better plan would be to write to the plate-makers and get them to let you know the cheapest and best method of sending the plates out to you, as per steamer the cost would come considerably less. (2) The firms you name are perfectly reliable, and the lenses may be relied upon for being genuine, and probably they would let you have a lens on approval if you deposited the money with us. Always pleased to help you.

**J. PROSSER.**—Both your prints are most fearfully over-printed, otherwise they are very creditable, considering what a short time you have been working. Let us see some more work presently, and do not print so deeply.

**G. BRITAIN.**—Dark-rooms are available at J. Brookes', 15, Flowergate, John Frank, 9, Bridge Street, W. W. Herbert, Dotchen's Yard, Baxtergate, and F. H. Bowers, Skinner Street. You cannot do better than stick to the plates you have been using; there are none more rapid, and our experience has been satisfactory with them.

**J. E.**—(1) The tree branches on the left are bad, and the fence is offensive. (2) Utterly without interest, and the railing is again very bad. (3) Good, up to competition standard. (4) Too patchy, and the lights too scattered, considerably under-exposed figures in too dark a shadow. (5) Better, but the figures are too evidently posed; the child should have been playing about, picking flowers, etc. Technically the prints are up to standard, artistically below.

**S. R. P.**—(1) We shall probably have an article on this subject shortly. A black background, and a vignette attachment in the camera is used, we believe. (2) The articles are not a reprint, although extracts may be utilised here and there. (3) The adapter is perfectly reliable and useful.

**H. A. SALWEY.**—We cannot unfortunately institute a series of comparative exposures. The table of speeds we shall hope to publish next week.

**TEP.**—(1) Development should be continued till the image "fades away" and the whole surface of the plate is black. (2) The duration of development should not exceed 5 or 7 min. at most.

**W. THOMSON.**—If you use plenty of clearing solution you could take the paper out into the light without fear, but if instead of using the ordinary fixing bath you will use the acid fixing bath, there will be no need of the clearing solution, so that you can fix at once and thus obviate the trouble of washing. By all means begin with a slow paper.

**F. HILL.**—There has never been any book published on this subject. Coat the back of your negative with matt varnish and make your solution of dye rather thick with gum water, then paint on with a brush. Some workers, on the other hand, first coat the film with collodion, then varnish thickly and paint on the varnish with dye. It is merely a matter of practice. Always glad to help you.

**T. C. MILLER.**—(1) Practically you may consider that the increase of focal length will require four times the exposure of the two combinations, actually about  $3\frac{1}{2}$  times. In bright sunlight on an open landscape, the exposure should not exceed about  $\frac{1}{2}$  sec. with  $f/22$ . (2) Ordinary drawing paper would answer, and would hardly require sizing, but a solution of 10 gr. of gelatine in water well brushed over it ought to be sufficient, or you may float the paper on gelatine solution for 5 minutes.

**BOTANY BAY.**—(1) If you measure the height of the room and focus an object at that distance you could rely upon its being sharp if stopped down well. (2) A wide angle would be a necessity to take in the whole of the ceiling. (3) The rule you want is this:—

Let  $D$  = the distance of object.

$f$  = the focus of lens.

$$\text{then } D - f = \frac{f^2}{x}$$

or as  $D : f :: f : x$

Or as the distance of the object (measured from a point one focal length in front of the centre of the lens) is to the equivalent focus, so is the equivalent focus to the extra focal length required. Suppose the height of room to be 12 ft. the camera will take up 1 ft.—then

$$132 - 8 = 124$$

$$\therefore \text{As } 124 : 8 :: 8 : x$$

$$\therefore x = \frac{16}{31} = \frac{1}{2} \text{ in.}$$

Your lens will then require racking out  $\frac{1}{2}$  in. more than the focal length to get ceiling sharp.

**W. J. BARTON.**—(1) Probably if you got in the shadow of anything, the plates would not be fogged, and even in bright moonlight the light is so non-actinic as to be harmless. (2) The xxxxx. plates are quite rapid enough for hand-camera work.

**A. E. W.**—You would find an R.R. of 5 or  $5\frac{1}{2}$  in. focus the most suitable. Whilst it is not necessary to always use  $f/8$ , it is certainly an advantage to have the extra aperture in reserve.

**R. GORDON.**—Your letter received; we have written to the firm named on the subject.

**A. TAYLOR.**—The new agents cannot yet be obtained in England. We have written to the maker, J. Hauff, Feuerbach, Wurtemberg, for samples. The prices are about 2s. 6d. per oz.

**E. H. GILBERT.**—If you mix your spotting colour with fairly strong gum water, it will dry bright, and not show. Some operators spot before burnishing, others only after mounting, which we prefer. To take clouds the best plates are undoubtedly Isochromatic, and a yellow screen should be used, stop down to about  $f/22$ , and 1-10th or 1-4th of a second is enough. Do not develop too much, but keep the negatives rather thin.

**A. F.**—(1) This is printed too deep, the clouds are far too dark. (2) Very fair. (3) Ditto. (4) Ditto, the Isochromatic plates are the best for this work, but require also a yellow screen; we think you are at fault in developing, you want to use a small quantity of reducing agent, pyro, etc., only, so as to keep the negatives thin and soft. The lamp you ask about is

Schirm's, a German one, but we have now the Todd-Forret, far more powerful, the Kolm, and also the Platinotype Company's; all these are fully equal to the German one.

**ARTUM MAGISTER.**—Tylar's Window Flind shutter. A. J. T.—(1) Under-developed, camera not straight. (2) Under-developed. (3) Ditto. (4) Camera not straight, under-developed. (5) Better. (6) Much under-developed. (7) Good, but too much foreground. (8) Under-developed. (9) This shows marks of unequal development. All your negatives are far too hard and black and white. You would have softer results if you add 30 gr. of ikonogen to the 20 oz. of No. 1 solution and use rather less No. 1 and more water. In 11 cases you want to develop longer.

**W. A. McCUTCHAN.**—Obtain some ordinary black varnish from any dealer, as used for ferrotype work, and try this. Prints will be sent back, we hope, next week. Entry form sent on.

**KALITYPE.**—No. 1 is considerably over-exposed, and fogged in developing. The yellowness on the plate is due to pyro stain, and the little metallic spot due to some dirt or impurity in the developer. No. 2 plate: there is absolutely no image on this plate, and we can only suggest that you either did not pull out the shutter of dark-slide, or else the light was not bright enough to affect the plate at all. The paper you name is one likely to suit a beginner, but, like everything else, it wants a little practice. Do you want negatives back? If so, send on stamps.

**H. J. BRISTOW DAVIS.**—(1) Flat, poor, and over-toned. (2) Better, but not up to the mark. (3) Decidedly better, but over-toned. (4) Very good, but would have been improved if rather more had been taken in, or if taken the other way of plate. (5) Good, but here a little sky would have been an improvement. (6) See remarks to No. 4. Nos. 4, 5, and 6 are up to the standard, and far superior work to 1, 2, and 3, which one can hardly credit are by the same worker. Do you want prints back?

**PLATES.**—We cannot find your plates, as you say you sent two half-plates, whereas we only have three very thin half-plate negatives, about which we have no letter.

**VERNON.**—The enlargement is over-exposed, and has a very unpleasant brown image. The cutting off of corners also is not pleasing. What developer are you using? Try ferrous oxalate, reduce the exposure slightly, and try for a black tone.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence. Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word: compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the **AMATEUR PHOTOGRAPHER**, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, **AMATEUR PHOTOGRAPHER**, 1, Creed Lane, London, E.C."

**Cameras, etc.**—Lancaster's quarter-plate Le Merveillex, with chemicals, complete, bargain, 22s.—Mapleston, 95, Lordship Road, Stoke Newington, London, N.

Lancaster's 12 by 10 Multum-in-Parvo camera, scarcely used, and three 12 by 10 porcelain dishes, price 25s.—P. Williams, 16, Mirabel Road, Fulham, S.W.

Lancaster's half-plate bellows camera, square, one double back, rising front, swing back, good condition, cost 50s., take 30s., bargain.—Hennis, 40, North Street, Colchester.

Half plate camera, square, with reversing back, all movements, three double backs, carriers for quarter-plates, quite new, £3 10s.—S., 5, Park Road, Crouch End, N.

**Cameras, Lenses, etc.**—5 by 4 Box camera with lens, f/3, and superior double back for 35s., or exchange half R.R. lens; no reasonable offer refused. J. Higginbotham, 16, Gough Street, Gray's Inn Road, W.C.

**Dark Slides, etc.**—Dark slides: six half good Instantographs, 6s. 6d. each; sent for approval.—Adams, Harold Wood, Essex.

**Hand-Cameras, etc.**—Presto camera, nearly new, three slides, ruby lamp, printing frame, in box with instructions, 6s. 6d., worth 12s. 6d.—Crane, Melrose Villas, Church End, Finchley, N.

What offers? Beck's quarter-plate hand-camera, as good as new, with six double backs.—H., 21, Kidbrook Park Road, Blackheath.

Hand-camera, Houghton's Automatic, in good condition and excellent working order, rapid rectilinear lens, Thornton-Pickard shutter, carries 12 quarter-plates, instrument has done good work, price £5.—J. B. Hartnes, 2, Royal Promenade, Clifton, Bristol.

Stereoscopic Company's Dispatch hand-camera, Newman's shutter, six double backs, cost £12 15s., equal new, price £6 10s.—B., 13, Canterbury Road, Brixton, S.W.

Optimus Ubique hand camera, 5 by 4 R.R. lens three double backs, view-finder, new this season, will take 57s. 6d.—102, Shaftesbury Road, N.

**Lantern Slides.**—Amateur wishes to exchange original lantern slides for others; paper proofs sent.—G., 38, Marchmont Street, London, W.C.

**Lenses, etc.**—Half-plate rectilinear, iris diaphragms, Black Band, 18s.; 7 by 5 R.R. movable hood. Waterhouse stops, finest quality, 21s.—L., 8, Kenilworth Road, Willesden Lane, London.

One Ross' rapid symmetrical lens, 6 in. focus, Waterhouse diaphragms, cost £4 5s., price £2 10s.—Howard, 49, Pier Road, Erith.

Lancaster's Instantograph lens and shutter, half-plate, equal to new, price 20s.—C., 10, Moss Lane, Leyland, Lancashire.

Taylor, Hobson's 8½ by 6½ rapid rectilinear, iris diaphragm, perfectly new, £3 10s.; Newman's shutter, whole-plate or 8 by 5, 32s. 6d.—Field, Montana, Blackheath, S.E.

**Negatives.**—Fifty instantaneous quarter-plate negatives, views of London, suitable for making lantern slides, price 1s. each; specimen and list, 1s. 3d.—J. Stabb, 154, Queen's Road, Bayswater.

**Sets.**—Lancaster's half-plate patent camera, two double backs, Ashford's tripod, with excellent R.R. lens and diaphragms, cost £7 10s., will exchange for quarter-plate and £3 cash; also No. 1 Kodak, with part film, cost £5 5s., sell for £2 15s.—Whitham, Fern Mount, Whalley Range, Padiham, Lancashire.

For sale, whole-plate camera, long extension, three dark slides, R.R. lens, and portrait lens with patent shutter, all in a leather bag, quite new, cost £18, will accept £12.—Write, Works, 63, Gayford Road, Shepherd's Bush, London.

Thornton-Pickard Ruby whole-plate camera, in perfect condition, with three double backs, and Thornton shutter fixed to front, turntable, and specially made tripod, Wray's 9 by 7 rectilinear, quite new, with iris diaphragm and strong canvas case, also whole-plate dishes, washing trough, large gas lamp, and six sheets Ilford paper, plates, chemicals, etc.; giving up photography; cost over £22, sell for £13.—Ponting, jun., Park Road, Southport.

For sale, a half-plate set by Marion, comprising camera with latest improvements, two extra fronts, three double slides, good three fold tripod, Optimus 7 by 5 R.R. lens, enclosed in solid leather case, 90s.; a Ross whole-plate portrait lens, with stops, price £7 10s.; Marion's cabinet portrait lens, 23s.; would exchange Ross or half-plate set for enlarging lantern.—Berry, 2, Ramilies Street, Great Marlborough Street.

### WANTED.

**Dark-room.**—Wanted, Davenport's Eveready dark-room, cheap for cash.—Aston, Princip Street, Birmingham.

**Hand-Cameras, etc.**—Wanted, a good hand-camera, also Thornton-Pickard shutter for 1½ in. hood.—Crampton, 6, Rocky Lane, Nchells, Birmingham.

Wanted at once, good hand-camera, lantern size, automatic changer; particulars and lowest price.—Smith, High Street, Morley.

**Sets.**—First-class half or full plate set, Ross, Stanley, or British make preferred, must be in good condition and moderate price.—H. Springfield, Strathaven, Lanarkshire.

**Tripod.**—Wanted, Kodak walking-stick stand; approval.—A. Huddart, Eskdale, via Carnforth.

**Bargains in Lenses.**—For sale, 15 by 12 Optimus wide-angle symmetrical, rotating stops, 10 in. focus, as new, take £4 15s., cost £9, cheap; 12 by 10 European Triplet, by J. Levi, No. 4 B, a really grand article, suit either professional or amateur for copying and other purposes, quite new, cost £9, take 70s.; Ross 10 by 8 wide-angle rectilinear, rotating, fine definition, with flap shutter, £3 10s.; 8 by 5 wide-angle lens, fitted rotating stops, f/16, rapid rectilinear, best condition, take 27s.; Ross' whole-plate rapid symmetrical, Waterhouse stops, works f/8, £4 12s. 6d.; whole-plate rapid landscape lens by Trench (this is really same as Dallmeyer No. 3), rotating stops, grand definition, works f/16, will cover 10 by 8, quite new, take 60s., cost more than double; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross' actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; whole-plate Suter No. 3, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; half-plate Dallmeyer rapid rectilinear, quite new, iris stops, movable hood, £4 17s. 6d.; half-plate wide-angle rectilinear, by Spicer Bros., fitted rotating stops, fine definition, as new, 27s. 6d.; cabinet portrait lens by Cox, rack focussing, Waterhouse stops, finest order, take 25s.; Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d. Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; half-plate Lancaster's Instantograph lens, iris stops and instantaneous shutter, as new, 15s.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by

Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, Corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Hand Cameras.**—No. 2 Kodak, quite new, fitted 100 films, rapid rectilinear lens, finder, and shutter, in leather case, £5 7s. 6d.; Facile, by Fallowfield, rapid rectilinear lens and shutter, carries 12½-plates, as new, £4 5s.; Optimus detective camera, by Perken, Son, and Rayment, Optimus rapid rectilinear lens, carries 6½-plates, covered black leather, take £4 4s.; Adams' and Newman's hand-camera, 1-plate, Taylor and Hobson's special rapid rectilinear lens, f/5, with extra changing box, to carry 24 plates in all, take £7 17s. 6d.; Shew's Eclipse hand-camera, half-plate, latest pattern, fitted, rapid rectilinear, lens, rotating stops, four slides, with carriers for either films or plates, the whole fitted in leather, covered carrying case, a real bargain, take £7 10s.; half-plate Rover, by Lancaster, quite new, iris stops, all same shutter finder, leather case, take £3 17s. 6d.; optimus magazine hand-camera, carries twenty-three quarter-plates, fitted Burysscope rapid rectilinear lens, instantaneous roller blind shutter, two finders, as new, take £5 15s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 17s. 6d.; and another, 15s.; Lu o hand-camera, by Robinson, Regent Street, quarter-plate rapid rectilinear lens, time and instantaneous shutter, finder, and leather case, carries 100 films, £4 10s.; No. 1 Kodak, as new, rapid rectilinear lens, instantaneous shutter fitted, 50 films, covered leather, in case, take 42s.; Adams' Ideal, covered leather, new few weeks since, very latest pattern, rapid rectilinear lens, carries twelve quarter-plates, two finders, etc., £5 17s. 6d.; Griffiths' 1-plate magazine hand-camera, carries twelve plates, changing bag, good lens, finder, etc., 22s. 6d.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, 32s. 6d.; Ariel hand-camera, Shew's eclipse pattern, leather bellows, quarter-plate, rapid rectilinear lens, rotating stops, Kershaw shutter, three patent Turnbull slides, quite new, take 57s. 6d. All above warranted in very finest order.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Cameras and Sets.**—Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide half-plate carrier and folding stand, as new, take £5 15s.; half-plate Hare camera, wide-angle, double extension, square leather bellows, all latest improvements, fitted Optimus rapid rectilinear lens, Hare's patent automatic changing box, carries 24 plates, three-fold stand, bayonet joints, solid leather case, and time and instantaneous shutter, grand lot, brand new, cost £13 13s., take £10 10s.; Lancaster's 1-plate special patent camera, brass bound, square leather bellows, two double slides, Lancaster's lens, shutter folding stand and case, take £4 4s.; 1-plate 1891 Instantograph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new. Half-plate Duchess camera, all latest movements, etc., Optimus rapid rectilinear lens, fine definition, Thornton-Pickard shutter (time and instantaneous), two double slides, three-fold stand and case, as new £7 5s. Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; half-plate Underwood's Instanto, warranted as new, reversing back, double slide, rapid rectilinear lens, and folding stand, 75s.; 1-plate special patent brass bound, conical leather bellows, fitted four single slides, really good lens, folding stand and case, lowest 37s. 6d.; 1-plate Underwood's instanto, finest order, changing box for 12½-plates, good lens, rotating stops, one slide, folding stand and case, 35s.; 1891 Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

*It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.*

OUT OF POSTAL UNION ..	" " 7s. 9d.....	" " 15s. 3d.

**TRADE ADVERTISEMENTS** are received up to Tuesday morning.

**PUBLISHING DEPARTMENT.**—All letters containing Subscriptions, Orders, Remittances, SALK and EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZEL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition, No. 139. —

"SEA PIECES OR RIVER SCENERY." Latest day, August 22nd. —

Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, September 16th.)

THE Photographic Convention was this year honoured with the presence of two well-known American workers, Miss Catherine Weed Barnes and Dr. Mitchell, and it has been suggested that a party of English photographers should visit the United States next year in connection with the Chicago Exhibition. Mr. H. Snowden Ward, the editor of the *Practical Photographer*, has been entrusted with the task of making the preliminary arrangements, and he says in an advance slip he has sent us:

"As regards the reception that would be accorded to an extensive party of photographers by their confreres across the water, we think there can be no doubt. Miss Catherine Weed Barnes assures us (unofficially, of course) that the two principal New York societies and the Chicago Camera Club will extend the heartiest of welcomes. Dr. Chas. L. Mitchell speaks with a like confidence on behalf of the influential society of Philadelphia. Mr. John Carbutt, whom we have since seen, assures us that the photographic manufacturers and merchants of the States will in every way aim at being of service to us; and we can personally speak for our brethren of the American photographic press—every one of them.

"It is too early to suggest even an outline scheme of what ought to be and can be done, but we think it should be possible to arrange for a general membership in the American photographic Convention, and so to make the grandest photographic gathering that has ever been held, or that will be possible for many years to come. We want everyone, therefore, who can, or even who may visit the exposition, to send us their names at once, with particulars of the dates, if any, between which their journey must fall, and with any suggestion they can make for the success of the scheme. We would then propose to arrange for a small Executive Committee to be formed in England, for a similar Committee in the States, and for a definite programme to be drawn up as far as possible. As it will be impossible, whatever arrangements we make, to fix a time that will be convenient for every one, we shall see that all possible privileges are extended to individual photographers as well as to the party. And we will undertake that the arrangements shall be duly printed and notified to all."

Such a scheme as this should meet with general support, and would lead, no doubt, to a much greater feeling of unity and brotherhood between our American confreres and ourselves. Mr. Snowden Ward, Memorial Hall, Farringdon Street, E.C., will be glad to give any further information.

WE publish in our correspondence columns an appeal from one of our readers in aid of a church fund, and we are sure there are many of our readers who will be glad to assist with prints, etc.

WE would again call our readers' attention to the "Holiday Guide" section of our "Annual" just published. This will be found invaluable to all wishing to combine

photography with their holidays, as it not only gives information as to dark-rooms, plates, and chemicals, but also will, in many cases, assist tourists considerably in finding the best bits and best time of day to photograph the same.

It has long been a question as to what amateurs should do with their negatives. Mr. Hamfeldt, of Helsingfors, Finland, now proposes to establish an International Photographic Exchange, the idea being briefly as follows:—

"If you are a photographer, or are in any way acquainted with this pleasing occupation, you will know that art collections are most valuable and sought after, and that people go long distances to study them, as being the best means of assisting the art-photographer in his work; so that a collection of the kind we propose to assist you in acquiring will, quite apart from the pleasures it will give, be of the greatest use to you.

"What we now invite you to do is to choose one or more of the best negatives you have, have copies—as many as you like—printed from them, and send these to us. In exchange for these you will receive a number of photographs, all different, but of as near as possible the same value, taken by photographers in all parts of the world.

"It is not proposed, however, to confine these advantages to people who practise photography, either for pleasure or for profit, as anybody will be able to obtain a collection in this unique and cheap way, by simply ordering from a professional photographer a number of unmounted prints, which can then be sent to us for exchange.

"Consider the interest of an International Album, and the value and pleasure it will give you. You will have the best photos sent you from every country in the world where this notice circulates; and as everybody will, in his own interest, send the best he can produce, it will be seen that the Exchange will be enabled to send the best photos procurable—in fact, photos that cannot in any other way be obtained. We advise you to commence at once, and follow up our suggestion, by starting your own International Gallery of the pictorial world and current events. It will grow in interest and value."

We shall be pleased to give any further information to our readers, or to place them in communication with the proposer.

THE HOVE CAMERA CLUB will hold an exhibition of photographs in connection with the Industrial and Horticultural Society, on September 21st and 22nd. The following are the classes and rules:—

#### OPEN CLASSES (FOR AMATEURS ONLY).

Class P 1, Set of six prints, landscapes, with or without figures; P 2, Set of six prints, marine subjects; P 3, Set of three prints, portrait and figure studies. First prize in each class, silver medal; second, bronze medal; third, certificate—presented by the Industrial and Horticultural Society.

P 4, Set of six lantern slides, landscapes or seascapes, taken within twelve miles of Brighton; P 5, Set of six lantern slides from hand-camera negatives; P 6, Set of six lantern slides, architecture, interior or exterior; P 7, Set of six lantern slides, subjects taken within the parliamentary borough of Brighton, three at least to be public buildings. First prize in each class, bronze medal; second, certificate. The best set in these classes will be awarded a silver instead of a bronze medal. The medals in classes 4, 5, 6, and 7 are presented by Mr. W. A. Hounsom.

#### HOVE CAMERA CLUB CLASSES.

P 8, Set of three prints, any subject. First prize, silver medal; second, bronze; third, certificate. Open to members of the Hove Camera Club only.

P 9, Set of three prints, any subject. First prize, bronze medal; second, certificate. Open to members of the Hove Camera Club who have practised photography only since January, 1891. Medals presented by the Club.

#### CONDITIONS.

(1) Exhibits must be the entire work of the exhibitor; exposure, development, retouching, printing, toning and mounting. (2) Photographs may be printed by any process, or on any material, but must not be enlarged, or from an enlarged negative. (3) No picture is eligible for competition which has previously received an award in any open class. (4) Exhibitors may enter more than one set in any class, but cannot take more than one prize in such class. (5) No name must appear on the photographs, but a *nom de plume* must be written on or attached to each frame or mount, which *nom de plume* must also appear with name and address on the entry form. If more than one set be sent in, each set must also be numbered. (6)

The judges have power to withhold any award if in their opinion the exhibits are not of sufficient merit. (7) An entrance fee of 61. for each class exhibited in (except classes 8 and 9) must be sent with entry form, duly filled up, to the Hon. Sec. of the Industrial Society, H. Emery, 142, Church Road, Hove, on or before Saturday, September 17th. (8) Photographs must be delivered at the Town Hall on Tuesday, September 20th, between the hours of 4 and 8 p.m. Lantern slides must be sent to 142, Church Road, by Monday, September 12th, at latest. (9) Exhibits from a distance must be sent, carriage paid, to 142, Church Road, Hove, Brighton, in time to be delivered on the days mentioned in the foregoing condition. (10) The slides will be retained for about seven days for the purpose of a public lantern exhibition.

THE Stockwell Floral and Industrial Exhibition will be held in the National Schools, Lingham Street, on Monday, August 1st, and two following days. There is a small section devoted to photography:—Class I, Set of three contact prints or enlargements; Class II, Two sets of four lantern slides. All exhibits must be delivered at the schools, in Lingham Street, between the hours of three and nine p.m., on Saturday, July 30th, and must be removed between the hours of nine a.m. and one p.m. on Thursday, August 4th. Intending exhibitors must fill in their names and addresses, adding the section and class under which they wish to exhibit on the forms, which may be obtained from the Secretaries, any of the Committee, or the district visitors. One prize will be awarded in each class, but a second prize may be given in any class consisting of more than twelve exhibits. Certificates only will be granted for exhibits in the trade of the exhibitor.

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

WE commence next week a series of articles upon "General and Photographic Chemistry," by Mr. E. C. Conrad, F.C.S., which we think will be found useful and instructive. Whilst there is always a great difficulty in making notes on the chemistry of photography interesting to general readers, we think in this case the articles will be found not too abstruse, nor yet devoid of practical interest, as formulæ will be included, and the main idea of the author, who is an analyst and chemist of high attainments, is to make the work practical.

We also commence a series of articles upon "Home-made Apparatus," which, judging from the success of Major Bruno's articles upon his hand-camera, will not be without interest to those of our readers who like to combine amateur carpentry and joinery with photography.

"Sun Pictures."—A very elegant contribution to the literature of illustrated magazines is the first series of "Sun Pictures," printed by Hazell, Watson, and Viney (Ld), and published from the office of the AMATEUR PHOTOGRAPHER. It marks the introduction into England, we believe, of the French method of illustrating letter-press by interspersed collotypes. The editor modestly claims "no merit beyond that of having plagiarised an idea of our French neighbours;" but the merit of his production is manifold, and will be acknowledged not only by photographers, professional or amateur, but by all lovers of the higher class illustrative art. There are two frontispieces in Woodbury-gravure, and thirty-six collotypes. Sixty-one towns through the United Kingdom and on the Continent are illustrated, the tourists themselves supplying the descriptive text. At 3s. 6d. it is cheap enough.—*Evening News and Post*.

## APPENDIX TO NOTES ON ENLARGING.

## INCANDESCENT GAS.

SINCE the note on the use of incandescent gas or the Welsbach light for enlarging purposes was written, we have made experiments with the improved form of burner and mantle supplied by the patentees of the Incandescent Gas Light Company, and has found that by the aid of the small blower and carburettor supplied the exposure for enlarging is considerably reduced; thus in enlarging with a 6-inch lens, a half-plate to four diameters, the exposure with an ordinary three-wick lamp was fourteen minutes, whereas with the carburetted air and mantle the exposure was ninety seconds on Eastman's bromide paper, B.

## BROMIDE PAPER.

## PRINTING BY CONTACT.

## PRELIMINARY CONSIDERATIONS, ESTIMATING EXPOSURE, ETC.

TO THE amateur engaged in business during the day bromide paper forms a ready method for obtaining prints quickly, as from twenty to thirty prints can easily be struck off and completed in an hour, all but the final washing.

Commercial bromide paper is usually issued in three grades—A, smooth surface and thin paper, suitable for mounting, and small prints; B, smooth surface and thick paper, suitable for larger prints and book illustrations; and C, rough surface and thick paper, suitable for enlargements. It is also issued in two degrees of sensitiveness, slow and rapid paper, and thus enables us by suitable modification of the development and exposure to obtain good prints from almost every class of negative.

The standards required for obtaining good prints are (1) a constant source of light, (2) correct exposure, (3) suitable paper, (4) suitable developer, (5) absolute attention to details and absolute cleanliness.

(1) *The Light*.—We may at once dismiss daylight as totally unable to fulfil the requirements of constant value. We must then fall back on artificial light, gas, lamp, candle, match, or magnesium ribbon, and the operator must be guided by the most convenient and the most suitable for his negative.

(2) *Correct Exposure*.—As in all photographic operations where there is an invisible image, correct exposure is a difficult thing to attain without some guide, such as experience or some method or trials. Our own method of estimating exposure when we require to turn out a large number of prints from one negative is to cut a sheet of paper into three or more strips, and selecting any portion of the negative which may be taken as typical of the rest, or in which we want to obtain detail, we expose the first strip, for thin negatives, 5 seconds; the second strip,  $7\frac{1}{2}$  seconds; the third strip, 10 seconds; whilst for dense negatives these times are increased to 10 seconds, 15 seconds, and 20 seconds, or even longer, the distance between the source of light and printing frame being twenty-four inches.

Dr. Herklotz Vos contributed the following valuable method of estimating exposure for bromide paper, to the AMATEUR PHOTOGRAPHER of November 23rd, 1888:—

"To obtain the best possible print you can from a negative with bromide paper, the exposure in most cases (unless the manipulator be very experienced) is largely arrived at by guess-work. Even the printed instructions supplied with the papers give you little or no help; no more do books; they only generalise vaguely. When once, however, the proper exposure for that negative has been ascertained, and some pieces of paper have been wasted over it, I have no doubt the careful worker makes notes of all the factors by which he arrived at his success, so as to be able not only to reproduce more good prints from that negative, but also to serve as a guide for printing from other negatives of a like density and colour. By my method I

can, with the practice I have had, determine correctly enough for good work the exposure for *any* negative right off. I do not say I don't have failures, but they are rare now. All will admit that the factors concerned are so various that it is doubtful if an absolutely correct method will ever be arrived at. I submit my results with all their imperfections for the favourable or adverse criticism of fellow amateurs. If we can get a constant or even fairly constant illuminant, it follows that by experiment we can establish a ratio between it and other illuminants which are also constant, and so knowing the exposure for any given negative with our standard illuminant, we can produce from that negative either bromide prints or lantern slides, enlargements, opals, and so on, working either by gaslight, daylight, electric or lime light, etc. We must, of course, take into account also the varying speed of the emulsion of the different papers, lantern plates, etc., and these are all ascertainable by experiment. To obtain, then, a primary standard of exposure to work from is the desideratum, and I will proceed to the lines on which I have worked to arrive at this end.

"The standards I use are—(1) a No. 5 Bray burner (burner tipped with white material, cost 1d.) at its fullest power of illumination, viz., full pressure at the meter and the tap of the burner turned down just sufficiently to avoid flaring. (2) Eastman's bromide paper, A, B, and C all being of the same speed (though I see by a report of a meeting of the North London Photographic Society, published in the AMATEUR PHOTOGRAPHER of the 19th October, that Mr. Bell-smith, of the Eastman Company, said that they make their paper in two speeds, and I gather, from his further remarks at that meeting, that what I have always been supplied with as just 'Eastman's bromide paper' was of the slower kind). (3) Iron developer, made up with saturated solution (as usual) of oxalate and iron, both rendered just acid with sulphuric acid (an important and not to be neglected point) in the proportion of one to four (also as usual), and bromide added in the quantity of one-fifth of a grain (two drops of a 10 per cent. solution) to each ounce of developer—which quantity of bromide is quite enough. I will mention modifications of this developer farther on. (4) A fixed distance of exposure to the Bray burner, viz., two feet. (5) A fixed scale of feet and inches, measured from the burner, and at right angles to the plane of the flame. This may be marked out on the floor, or if the burner be fixed near a wall, marked on that wall, or the marks made on a piece of wood, or, best of all, a tape measure, these latter being fixed on a level with the burner.

"In all these instances the fixed scale to be six feet, measured from the burner, and the intervening feet and inches also marked out. (6, and last) A piece of opal glass, purchased as 'flat ground-glass opal plaques for painting on.' Mine was obtained at Reeves's, in Cheapside, cost 8d., and is of the size of a half-plate negative, which I find the most convenient size. The glass is quite smooth and transparent on one side, but the other is ground very fine, and has a layer of white opal on it. It is in the employment of the Bray burner, the scale of six feet, and the opal glass that the specialities of my method exist. If a negative be held up to any gas flame at its fullest, and the negative be not too dense, the details will be seen through it at a distance of many feet, perhaps ten or fifteen feet, but by intervening the opal glass between the negative and the light it will be found that details will now become visible according to the density of the negative taken in conjunction with the distance at which it is held from the flame. I have found that the opal glass is the best medium for this. Plain ground glass is too thin, and lets too much light pass through it, but with the opal glass (which is ground on one side, as well as being somewhat dense by means of the opal in it) my object is attained, the details of the negative, too, standing out clearly defined, with the pure white opal as a background. My *modus operandi* is as follows: Place the gelatine surface of the negative you wish to print from on Eastman's bromide paper, in contact with the rough and opal side of the plaque, holding the two just before you in front of the Bray burner, and in such a manner that you will readily ascertain the distance at which you are holding it from the flame. Hold them, say, at 3 or 4 ft. from the burner. Now if the details cannot be seen, approach the light until the details just become visible; for example, say in a view, until the markings of a stone or brick wall, or the details of leaves, or what not, are just seen. Then for every inch distance the negative and opal glass are from the six-foot mark, when details become just visible, give one second of exposure to obtain a print on Eastman's bromide paper, the distance at which you must, during exposure, hold the negative (placed in contact with the paper in a printing-frame), being 2 ft. from the Bray burner. Example: Details are just seen at 2 ft. from the 6 ft. mark (that is 4 ft. from the burner); give in this case 24 sec. exposure (there being 24 in. in 2 ft.) I have arrived at the 6 ft. scale and the 2 ft. distance for exposure by experiments often repeated. It will be evident that the denser the negative the closer you will have to be to the flame to see its details, and the longer the exposure in consequence, and *vice versa*. If now the negative be a very thin one (and such negatives will give

good bromide, but not good silver prints), details with the opal glass will be seen at a distance of much more than 6 ft. from the flame; in this case the *maximum* exposure is 2 sec. at 2 ft. from the burner as before; and for the other extreme, a very dense negative, or one too much intensified or fogged (all faults in the negative, as also in the case of the very thin one), and you have to go *into* the flame almost to see details, give the whole 72 sec. exposure (72 in. in 6 ft.), but hold the negative at  $1\frac{1}{2}$  to 1 ft., instead of at 2 ft., from the burner, in exposing the paper. Some practice will be required to estimate exposure for these faulty over-dense negatives, hence I state  $1\frac{1}{2}$  to 1 ft. As to the colour of the negative: if it be a yellow (pyro developed) one, you will have to approach the flame to get details more than if it be a black (iron, or beach, or hydroquinone developed) one. The yellowish actinic colour, therefore, is not of importance. (I would mention, in passing, that under-exposed negatives having large masses of clear glass in them are not suited for bromide printing, nor for silver printing either, for that matter. Negatives with plenty of detail, and I think preferably iron developed, are the best for this work; and an over-exposed negative will give good results, though not if printed in silver). Further: in the case of dense negatives 10 or even 20 sec. exposure in excess of that ascertained by the opal glass will not spoil the picture, and if in any doubt, give this excess. With thin negatives, however, the ascertained exposure should be adhered to strictly, or even lessened, as it is very easy to over-expose a thin negative."

With regard to Dr. Vos's method, we may say that we worked with it for some considerable time, and can therefore testify as to its value from practical experience.

The following suggestions as to the possibility of obtaining good prints from every class of negative must, of course, be taken with a big grain of, not salt, but experience; in fact, with bromide paper as with every other photographic process each operation must be attended to with a liberal admixture of intelligence. Never expect things to do themselves, but do them yourself, guiding them by your hands and brain.

We will assume in the first instance that we have three negatives to print from, the one a weak, thin negative without any contrast, and yielding as a rule flat, foggy results on other papers; what are we to do to obtain good bromide prints? Choose a paper and method of exposure which will increase contrast, select a slow brand of paper (for various tested speeds of bromide paper, see p. 337, vol. xv.), place it in contact with the negative, and having estimated the exposure, we will say by Dr. Vos's method, and found it to be about five seconds at two feet from the gas burner, remove the printing frame to a distance of four feet, and calculating the increased exposure necessary (see p. 337), which will be twenty seconds at the greater distance, cut the exposure rather short and give only seventeen to eighteen seconds, and then modify the developer as given in the next chapter.

Our next negative is an ordinary negative with good gradation, yielding good prints with suitable treatment on any paper; then choose any but a rapid paper, or even this if we decide that a slight lessening of contrast will be an improvement, and give it a normal exposure at the normal distance, and a normal developer.

The third negative is one full of harsh contrasts which nothing will subdue; then choose a rapid paper, and give a full exposure at the normal distance, and modify the developer as described in the next chapter. Where sharply defined masses of dense deposit occur in a negative, our practice is to use an ordinary wax vesta, and, igniting this, to pass it evenly and regularly all over the negative at about half an inch from it, and then to move the lighted match to and fro over the very dense parts, thus giving them more exposure than the thin parts. Working thus we have found we can obtain far more harmonious results than by the ordinary method of exposure, and an ordinary wax vesta is quite sufficient to expose a half-plate print in this manner, and then there will be a little piece to spare, but the whole match is required for a whole-plate, using it as

close as possible. Where extreme contrasts exist, it may even be advisable to use a more powerful light of greater penetrative power such as magnesium ribbon, about one inch being the requisite quantity for a normal negative, moved to and fro at a distance of three inches from the glass.

## Letters to the Editor.

### HINTS TO BEGINNERS.

SIR,—I regret that I have not been able to reply to Mr. Forret's letter in time for your issue of last week. All said and done, what Mr. Forret has convicted me of is principally an inaccuracy, or rather a want of lucidity, in expression. I do not for one moment wish to minimise my error, as that very want of lucidity might lead others astray, and I am obliged to Mr. Forret for pointing it out, and moreover for saying that, as regards hypo, an unequal saturation (if this is the correct term) is practically of no importance in photography. Still, the point I wished to insist on remains, namely, the advantage of filtering the fixing solution for negatives, as hypo as received from the dealers often contains insoluble foreign matter, which does no good, if it does no harm, to negatives. As regards the gold solution referred to, being no chemist, I was obliged to accept the dealer's explanation; all I know is that the last 2 drms. in the bottle of the gold solution apparently contained more than 2 gr. of chloride of gold, as my prints were spoilt by rapid and over-toning. Since I have given the bottle a shake before using this has not recurred. As to the acidity of the borax solution, I can only go by the litmus paper, which has turned red more than once. The slow action I referred to was in the use of the stock solution *not strengthened with fresh gold*; and I think if Mr. Forret will experiment with his stock solutions he will find that if a print is left about half an hour in an old solution, it will acquire a very decent tone, unless, perchance, the gold has been worked out to the last trace. My remarks in the article would have been more lucid had I used the words, "without the addition of fresh gold." My method of compounding the toning bath is simply a matter of convenience. My advocacy of hot water was to hasten solution. Having but little time to devote to my favourite pastime, I cannot be everlastingly stirring, and shaking, and waiting for the salt to dissolve in cold water; nor have I the time to prepare my fixing bath for prints beforehand. Hot water saves time where the chemicals are required in solution quickly. I once made a toning bath with cold water with the finest powdered borax obtainable, and I was never so tired of anything in my life, it was so slow in dissolving. The hint about ferrous sulphate is good; I was not aware of its decomposing under the action of hot water, but I always, it so happens, make my solutions of this drug with cold water.

To conclude, I wish that more of your readers would follow Mr. Forret's example, and criticise articles, letters, and answers to correspondents in the manner he has criticised my little article. I have often noticed statements and formulæ in your paper which have appeared to me to be inaccurate, and which I have wished to enquire into, but that I have so little time at my disposal.

Thanking you for the space you have so kindly accorded to this discussion, I remain, etc.,

NOVOCASTRIENSIS.

### BLISTERS.

SIR,—As many complex suggestions have been put forward on this subject, will some of your readers try the following?

Take no notice whatever of blisters appearing, but when the prints are finished washing, lay them one by one face downwards on a piece of glass about an inch larger all round than the biggest size, and slightly overlapping each other in different directions. Then take a clean soft towel and press out the bulk of the water, after which put half a dozen sheets of blotting paper on and gently roll them, withdrawing the bottom wet sheet each time. Apply the mountant after all moisture is apparently removed, and, having placed the print in its position on the mount, roll again, and let them lie all night and next day if possible under a heavy weight.

I can show dozens of prints which were very badly blistered while washing, and in which it is impossible to find a trace of these unwelcome intruders.

THE BARON.

SIR,—As my Premier sensitised paper has several times been referred to in this correspondence, kindly allow me to explain that when supplied in full sheets it has always been entirely free from liability to blister and from offensive smell, but when ordered in cut-up sizes, I have hitherto for convenience sake supplied a well-known commercial brand of paper. However, I have now arranged to cut up and pack my own Premier sensitised paper in all sizes, so that in future this will be as free from blisters as the full sheets have always been.—Yours, etc.,

JONATHAN FALLOWFIELD.

#### AN IRISH TRIP.

SIR,—If there are any photographers wandering about the north of Ireland they would do well to pay Portsalon a visit if they want a comfortable hotel, good air, good bathing, mountainous scenery, and good golf links. Portsalon is on Lough Swilly, and is reached from Londonderry by taking train at 11 a.m. to Fahan and steamer, every Tuesday and Friday. A pleasant sail up Lough Swilly brings them to Portsalon. There are some remarkably fine natural arches in the cliffs here, made by the action of the sea. Golfers will find splendid links of eighteen holes, three miles in length over a most varied course by the sea, which seems as if it was formed by nature purposely.

VIATOR.

\* \* \* \*

#### INDUSTRIAL COMPETITION, NEW SWINDON.

SIR,—Having got together a good sum towards building some much needed Sunday schools, but still a little more required before we can start, we are getting up competitions in various things, including photography, for small prizes, the articles to be afterwards sold. Doubtless there are among your many readers many who have good plates of notable places or views from whom I would ask for a few prints, mounted preferred, either for or not for competition. A gentleman who is an entire stranger to us has consented to act as judge. Entries close August 17th. I will gladly give any further information to any who will kindly help us in either way.—Yours, etc.,

A. SHIRLEY.

77, Westcott, New Swindon, Wilts.

#### INDUSTRIAL COMPETITION, IN AID OF THE BUILDING FUND OF S. MARK'S SUNDAY SCHOOLS, NEW SWINDON.

Entrance free. £10 in prizes.

Competitors are asked to make any article or articles they choose, and give them to be sold in aid of the above object.

Prizes will be given to the makers of the best articles in the various classes (should there be in any one class or division ten or more competitors under the age of sixteen years, they will form a junior class, in which an additional prize of 10s. will be given.) Should there not be ten competitors in any one division, the prize will be reduced to 10s.

CLASS IV., PHOTOGRAPHY.—Secretary, Mr. A. Shirley, 77, Westcott Place, New Swindon. Prize, £1, and 10s. given by the judge.

All articles must be sent (the name and address of the maker legibly written and attached to each article) to the secretary of the class or division to which they belong; or direct to Miss Swinhoe, Park House, New Swindon, on or before Wednesday, August 17th, 1892.

\* \* \* \*

#### ALGERIA.

SIR,—I see by the last number of the AMATEUR PHOTOGRAPHER that you ask for short notices about places of photographic interest. I wish the following may prove useful.

The place I should like to mention is "Bone" (Eastern Algeria). It is a town of some thirty thousand inhabitants, a fair proportion of which are Arabs and Moorish Jews. The neighbouring country is as picturesque as possible, combining forest, plain, mountain, and sea-coast scenery at once. Tolerably good roads radiate in every direction, and the Bone-Guelma railway reaches hence to Tunis on one side, and Constantine on the other. One may even have a trip to the Biskra Oasis and the Sahara, *via* Bone. Lines of steamers go all round the coast on each side, stopping two or even three times per day at small but interesting towns.

The light is splendid, at least during the spring, summer, and autumn months. Clouds may be mentioned as very scarce. Hand-camera work is rather easy here, as far as I may judge.

Isochromatic plates should be secured before starting, to be able to take some of the people's variegated dresses.

No monuments to speak of, excepting some little Mohammedan *Koubbas*, with their round white domes of dazzling brilliancy.

But those are rather difficult to get, owing to the greenness of surroundings. The Eolough mountain will yield many a charming plate to the "alpinists" photographer.

There is only one drawback. From the first of July Bone may be considered as a very warm place; and when sirocco is blowing the heat is intense. The best time to pass here would be the second half of May and the first of June.

Three lines of steamers, one of which is the Transatlantique, reach Bone from Marseilles. There is a departure almost every day in the week. The Monday boat stops for some hours at Ajaccio (Corsica).—I am, etc.,

EUGENE.

## Elementary Photography.

By JOHN A. HODGES.

### CHAPTER XXVI.—(CONCLUSION.)

IN the foregoing chapters I have endeavoured, as concisely as possible, but without omitting anything which would be useful to the beginner, to describe the actual procedure necessary to successfully carry out the various processes in ordinary use for the production of photographs at the present time. Much more, no doubt, could be usefully written on some of the topics dealt with, but I have endeavoured to deal with each branch of the subject in such a simple manner as to enable the youngest or most ignorant reader of the AMATEUR PHOTOGRAPHER to obtain an intelligent grasp of it, and I have from time to time given references to authorities, so that the reader may, if he so desires, further extend his knowledge.

There is a mass of literature upon the subject, but much of it will be of little practical value to the student; he must therefore learn to discriminate between the wheat and the chaff. In particular much that is profitless has been written upon the artistic possibilities of photography, and the reader who seeks merely for instruction will find all that he will require, from a photographic point of view, in the works of H. P. Robinson, on the subject, who, besides being a photographer, is a painter of no mean ability.

Turning to the technical aspect of photography, the writings of Captain Abney deal most exhaustively and completely with the whole subject, and I have to acknowledge my indebtedness to them. To "Photography with Emulsions" I have already referred; his "Instruction in Photography" and "Treatise on Photography" should also be studied. The chemistry of the subject should not be neglected, and Hardwick's "Photographic Chemistry" and J. T. Taylor's "Photographic Chemistry" should both be procured. The latter author has also recently written a most valuable work upon "Photographic Optics." As a book of reference E. J. Wall's "Dictionary" will be found extremely useful, and the same writer's "Photographic Procedure," now appearing in these columns, bids fair, from the exhaustive manner in which it deals with each topic, to be even more so. A knowledge of the history of photography will be gleaned from a little book by Mr. Werge, entitled "The Evolution of Photography." The foregoing books may justly be termed standard works upon photography, and would form the nucleus of a good reference library. Improvements have taken place in photographic methods during the last few years by leaps and bounds, but although it is hazardous to attempt to prophesy as to the rate of future progress, yet it would appear that for some time to come further advancement will proceed more slowly than in the past. Improvements in processes and in methods, however, continue to be made, and in order that these may be intelligently followed it becomes necessary to read the current literature upon the subject. Therefore the beginner will derive the greatest

possible benefit by becoming a subscriber to one of the weekly papers devoted to photography. Of the four or five of these which are now published, the AMATEUR PHOTOGRAPHER is perhaps most suited to the particular requirements of the amateur; it is, in fact, the only paper which is exclusively an amateur organ, though its pages are by no means shut to the professional, some of whom, bearing honoured names in photographic journalism, being constant contributors to it.

I have endeavoured throughout to treat every subject upon which I have written in the most elementary manner possible, using language as free from technicality as I could command, and the system has been similar to that which I should have adopted had I been imparting the information orally. The instruction has been progressive, therefore I would urge upon the beginner to first read the book from cover to cover, and then, commencing at the beginning, follow the procedure laid down to the letter, and chapter by chapter, in their proper sequence. The principle which I have endeavoured to follow in imparting the information which I was seeking to convey, was to give one well-tryed and successful method of working, and one only. In photography, as in other things, there are more ways than one of arriving at the same result, but ringing the changes on developers, plates, and processes is the worst possible course which can be adopted. Modesty, I am aware, is a very essential qualification for an author, but I may be permitted to say that every process and mode of treatment of plate or paper mentioned in these pages has been practically tested and found not wanting by the writer during a photographic experience now running rapidly, alas! into two decades.

Although, the introduction of the gelatine process has made successful photography far easier of attainment than in the days of collodion, yet the reader will at times meet with disappointment and non-success. When it is remembered that the same thing not unfrequently happens to even the most experienced, it will be understood that something more than the mere "pressing of the button" is required on the part of the learner, if he is determined from the beginning to himself do the rest rather than depute it to others. Let him not, therefore, be discouraged by failures, but begin again from the commencement, and endeavour to trace the cause of the trouble to its source. Failures, if regarded intelligently, are helpful rather than retrogressive, and may even be regarded as stepping stones to advancement and invention.

If near the headquarters of a photographic society, become a member of it. Even though it be a small affair, and its members not more experienced than yourself, you must be the gainer, rather than a loser, by your intercourse and exchange of ideas with them. Always remember when real difficulty occurs, the surmounting of which seems impossible, that a plain statement of the facts addressed to the Editor of a photographic paper will always meet with kindly and efficient attention. In regard to the practical utility of the query column, I am extremely dubious, for the questions are sometimes replied to by those whom the answers given stamp as being unqualified to convey the information sought for. Indeed, one may sometimes see queries of quite an elementary nature, under the same initials or *nom de plume* as those appended to answers to questions previously put.

In conclusion let me again remind the reader that there is no royal road to success in photography, he must learn to walk before he can run, but if that which I have written proves of assistance in guiding his footsteps, my object in writing will have been fulfilled.

## Apparatus.

### MERLIN'S HAND CAMERA.

P. MERLINI, of 34, Red Lion Street, Clerkenwell, E.C., has shown us a very neat and convenient hand-camera he is just placing on the market.

It takes the usual box form, and measures  $10\frac{1}{2}$  by 7 by  $5\frac{1}{4}$  inches, and is made of ebonised wood. It is fitted with three mahogany double dark slides of the solid type, a rapid rectilinear working at  $f/8$ , and a Thornton-Pickard shutter.

To a great extent it carries out Major Bruno's ideas, although actually it was made some time before his articles appeared. It possesses a rising and cross front, a swing back and focussing screen, and a focussing indicator. It is practically an ordinary camera, and may be used on a stand in the ordinary way, and yet forms an efficient hand-camera.

The maker offers the three double backs or twelve single slides, the camera, shutter, and lens at the reasonable price of £4 10s., and at this price it should find many friends. It is a well-made, capable instrument and its uses are practically universal.

### WAGNER'S TRANSPARENT ALBUMEN COLOURS.

Mr. C. A. Rudowsky, of 3, Guildhall Chambers, Basinghall Street, E.C., is introducing the above colours for tinting photographs. They are all liquid colours, ready for use, and work satisfactorily on any surface and dry with a gloss, and are perfectly transparent.

Permanent albumen water-colours and albumen spotting colours are also offered by the above and should be found useful not only for prints, but also for lantern slides and transparencies.

### THE NEWMAN SHUTTER.

Messrs. Newman and Guardia, of 71, Farringdon Road, E.C., have introduced an improved form of this well-known shutter, which is now much neater in appearance, lighter, and the working parts are counterbalanced. This shutter has long been a favourite, and we have found it a very useful and reliable instrument.

The following is the list of speeds and prices, etc., of the new shutter.

Size.	Aperture up to inches.	Improved Form.	
		Speed : Seconds.	Price each.
$\frac{1}{4}$ to $\frac{1}{2}$ pl.	$1\frac{1}{2}$	1 to $\frac{1}{100}$	32/6
$1/1$ "	$1\frac{3}{4}$	2 " $\frac{1}{200}$	35/-
$9 \times 7$ "	$1\frac{1}{2}$	2 " $\frac{1}{200}$	37/6
$10 \times 8$	$1\frac{3}{4}$	2 " $\frac{1}{200}$	40/-
$12 \times 10$	2	2 " $\frac{1}{200}$	45/-

Complete with ball and tube,  $f/11$  stop and fittings.

THE photograph of lightning reproduced in our last number was taken by Mr. William Rice, not E. Rice, as stated.

DEWSBURY AM. PHOT. ASSOC.—The Hon. Secretary, Mr. George Kilburn, requests us to notify his change of address, which is now 35, Grey Street, Leeds Road, Dewsbury.

## ILLUSTRATED SUPPLEMENT,

## Monthly Competition, No. 37, "Portraiture and Figure Study."

## CLASS I.

1. GEAR, J. H. (London).—"Fishing in Preserved Waters." Taylor and Hobson,  $f/16$ ; 1 sec., June, sun through light clouds, 7.15 a.m. This is a very carefully thought out and happy study. The competitor informs us that he had to obtain permission from the Commissioner of Police to photograph in Trafalgar Square, and that the gentleman in blue was asked to kindly take the little culprit's name and address, and the boy, the competitor's nephew, was told to "cry hard." The result fully justifies the care expended, and deservedly takes the Silver Medal. A 12 by 10 platinum print.

2. EVANS, J. W. (Wolverhampton).—"A Bit of News."  $F/32$ ; about 6 sec. October, rather bright, 12 o'clock. This competitor has long been in the front rank, and we congratulate him on winning the Bronze Medal. A whole-plate, plain-paper print of very pleasing tone.

3. PENNINGTON, R. O. (Kendal).—"Dale Folk." Dallmeyer's R. R.,  $f/32$ ;  $1\frac{1}{2}$  sec., June, sunlight, 2.30. A half-plate platinotype (hot bath) print, which is a little flat; probably the new cold paper would give a better result.

4. BRANTHWAITE, R. W. (Herts).—"After the Dance." Ross' single landscape,  $f/32$ ; 12 sec., May, bright light, 11 a.m. A very pleasing, soft study, probably cut down from 10 by 8 print. It is just a trifle over-printed, but shows very careful work.

5. TIMS, J. (Surrey).—"Happy Childhood." Optimus Euryscope,  $f/32$ ; about 2 sec., May, in shadow, with sun glinting across path, about 10.45; half-plate; hot bath platinotype. Technically a very fine print, of a warm, pleasing tone, and a characteristic bit of "happy childhood."

6. HERBERT, W. (Cardiff).—"The Morning Bath." Argus R. R.,  $f/21$ ; half sec., July, fairly good light, 8.30 a.m.; Ilford ordinary; platinotype, hot bath, sepia; half-plate print. Technically good, but the three pictures and the three figures are a little bit too formal.

7. KENWORTHY, J. W. (Ashton-under-Lyne).—"On the Steps of a Warwickshire Cottage." Dallmeyer wide-angle landscape,  $f/16$ ; April, fair light, 3.30 p.m.; platinotype, hot bath; whole-plate print. A

homely old body, standing at a cottage door, but too evidently put there, and the apron is too glaringly white, and immediately attracts the eye as the principal object.

8. PAINT, E. R. (Miss) (Guernsey).—"Returning from Milking." Instanto,  $f/32$ ; 2 sec., June, bright light, 7.15 a.m. A half-plate silver print, far too dark in the right-hand corner, and wants clouds to relieve the white sky.

9. SEVERS, J. (Kendal).—"Our Pets." Ross single,  $f/15$ ; 1-10th sec., April, sun shining, 3 p.m. "Although the sun was shining I preferred to take the subject in the shade." This quarter-print is spoilt by some curious-looking lines across the top and bottom; the former might well have been cut off, but the latter should have been avoided somehow. A very soft and delicate print; the expression on child's face and portrait of cat are very good.

10. PRICE, A. R. (London).—"Don't Snatch!" Beck R. R., 9 in. focus,  $f/8$ ; half sec., latter part of May, very good light, 9.30 a.m. A very soft little quarter-plate print on Xylonite film, and would have taken considerably higher rank, only that the background does not sufficiently cover the wall and window. The idea of a little girl holding a piece of bread and telling "doggie" not to snatch is very well carried out.

11. NICHOLLS, A. C. (Cheltenham).—"An Impromptu." R. R. Taylor and Hobson,  $f/11$ ;  $1\frac{1}{2}$  sec., September, diffused light, open air, 3 o'clock. A very good attempt at a character sketch of "The Three Little Maids from School;" half-plate chloride print.

12. NEWMAN, G. J., JUN. (Cheshire).—"Summer Days." Ross's R.S.; 3 sec., June, bright light, 11.30. Slightly

over-printed, or else the negative wants intensifying slightly with mercury and sodium sulphite. The print is just wanting in brilliancy.

13. SAMPSON, E. (near Sheffield).—"Crossing the Stream." Wray's 5-inch focus landscape,  $f/16$ ; 4 sec., June, dull light, 6.30 p.m. A very pleasing little quarter-plate print, but the figures are in the weakest part of the picture—the centre.

14. COPEMAN, R. W. (Blandford).—"Tired." Fallowfield R. R.,  $f/16$ ; 2 sec., April, dull light, 1 p.m. "The subject is just over 90 years of age." A half-plate bromide print. This would have been

Silver Medal.]

"FISHING IN PRESERVED WATERS."

[J. H. GEAR.

[COPYRIGHT.]

far more effective if the clay had dropped on to the ground, and the old man's lower jaw had dropped. The print is soft and pleasing.

15. BLACKWELL, G. W. (Sheffield).—"The Modeller." Rectilinear; 10 sec., June, dull light, 12.30. Half-plate silver print. A very good

No. 2.]

"A BIT OF NEWS."

[J. W. Evans.

(BRONZE MEDAL.)

study, but the lighting is curious, and one wonders whether the modeller would not have turned his clay to instead of from the light.

16. POLLARD, MRS. M. M. (Cheltenham).—"Buy my Pretty Flowers." Lancaster,  $f/20$ ; 3 sec., September, 3 o'clock. Half-plate silver print, showing unequal toning at the edges, and the flower seller is far too well dressed for the character. The apron is too white.

17. ARNOLD, J. O. (Sheffield).—"Olive." Wray R.R.,  $f/8$ ; 2 sec. April, strong sunlight, about 4 p.m.; matt, silver half-plate print not toned. "Taken in room lighted with one window, without reflectors." This at once strikes one as being a very good representation of a framed portrait; it is soft and pleasing in tone, but the expression on child's face is not happy.

### CLASS II.

1. BENTLEY, H. C. (Louth).—"Rustic Courtship." R.R.,  $f/16$ ;  $\frac{1}{2}$  sec., May, good light, 4.30 p.m. A very good print, but which is a little spoilt by the formal lines of the building in the background, and the straight line of the tree on the right, and the girl's dress is too white.

2. ST. CLAIR, L. M. (London).—"Returning from Market, Nepal." Shew's Eclipse hand-camera and lens,  $f/11$ ; about  $\frac{1}{2}$  sec., October, sunshine, 5 p.m. A very clever little quarter-plate study full of sunshine and brilliancy.

3. JONES, W. LLOYD (Cheshire).—"A Cornish Fishing Crew." Dallmeyer R.R.,  $f/11$ ; off and on, August, strong diffused light, about 10 a.m. Another very good print, but could have been considerably improved by a little more judicious grouping.

4. WILLIAMSON, J. "Heave, Yoho!" June, 11 a.m., bright sunlight; R.R.,  $f/11$ ; 1-15th sec. A very pleasing study of fishermen, although the print is a little bit yellow and wanting in brilliancy.

5. LANGTON, A. (Ilfracombe).—"Crew of 'The Polly.'" Taylor R.R.,  $f/22$ ;  $\frac{1}{2}$  sec., bright sunlight, noon. Technically a very fine

print, though the repetition of crossed arms and legs in the foreground is not pleasing.

6. TENERSHAM, R. K. (London).—"Black and White." Ross' R.S.,  $f/11$ ; cap off and on, mid-day, Christmas, India. Very good print, and the child is exceptionally happy in pose and expression.

7. SMITH, H. S. (Bradford).—"Our Skipper." Beck's R.R.,  $f/16$ ;  $\frac{1}{2}$  sec., June, good light, about 12 o'clock. "The face is untouched. The tarpauline was a bright yellow, which of course is rather a severe test for an ordinary plate." This print is a little too hard, and the branches of the tree should have been painted right out, and replaced by clouds.

8. RUSHAND, W. (Chester).—"Friends." Taylor and Hobson,  $f/16$ ; 1 sec., August, dull, 3.30. A half-plate chloride print on chloride paper, showing very careful technical work, but not improved by the vignetting, and the dress is too white.

9. JACKSON, J. H. (near Leeds).—"Drinking Time." Ross' R.S.,  $f/11$ ; cap off and on,  $\frac{1}{2}$  sec., June, fair light, 10.30 a.m. This is a half-plate print from a negative insufficiently developed with hydroquinone or else over-printed. It is sadly lacking in brilliancy.

10. C. P. BOLTON (Waterford).—"Young Wood-Rangers." R.R.,  $f/11$ ; 3 sec., June, bad light, evening. An opportunity missed; had the children been gathering the flowers or arranging them, it would have scored well. It is now nothing but a group.

## The Photographic Convention.

### INDIVIDUALITY IN PHOTOGRAPHY.

BY H. P. ROBINSON.

IN a recent number of *Blackwood's Magazine* an ingenious writer tries to show that the one thing more than another that now represents primitive man is the baby, and that the nineteenth century British baby differs very little from the savage child of, let us say, a couple of hundred thousand years ago, for the baby is nearly a quadruped, and is a reckless creature devoid of conscience. It is,

No. 3.]

"DALE FOLK."

[R. O. Pennington.

(CERTIFICATE.)

perhaps, a knowledge of the fact that babies are all alike that enables photographers, as it is libellously said, to make the negative of one of the species satisfy the yearnings of many mothers. Now, photography is certainly somewhat like this view of the human

race in the respect that its immature productions are all alike, and it is not until they grow up and acquire a conscience or soul that they differentiate and show individuality.

Of the immature there is no end, but a wise and invariable provision of nature checks over-production. Nature is always wise, but has no mercy—

"So careful of the type she seems,  
So careless of the single life ;"

and, seeing that the world would be overwhelmed by immature photographs, sent beneficent fading to destroy them (always, as in other departments of nature, "so careful of the type," sparing a few) until the art grew old enough to possess a soul or conscience, and then permanent methods were given to us ; and even now we sometimes feel inclined to paraphrase the wisdom of Mr. Whistler, and say modern photographs do not fade, and therein lies their deep damnation. This wonderful preservation of a few in all their pristine freshness is suggestive of a special providence, for according to the scientists, who are, of course, always right, like methods should produce like results, and not one of the old prints should have escaped.

Now, evidence of soul or conscience in a picture is art. Yet there are those who will not recognise that we have a soul, but, like Mr.

No. 4.]

"AFTER THE DANCE." [R. W. Branthwaite.

Gilbert's mechanical figures in the *Mountebanks*, are only stuffed full of badly-made machinery that sometimes runs down, and always moves with a jerk ; and I am not sure we are not suspected of trying to adopt the "put a penny in the slot" business to the fine arts.

It is a favourite reproach with the opponents of photography as a picture maker that its results are all alike ; it is one of the triumphant proofs of those who will not admit that photography is an art that the unthinking machine makes all its products to the same pattern ; that there is no intrinsic evidence in any photograph of its maker. They will no more believe the plainest evidence to the contrary than those of old would believe the angels. They say we are mechanical, and it is of no use pointing out that this wild assertion is obviously untrue ; we hear it over and over again, sometimes from one who knows it is not true, at others from those who are simply ignorant and cannot learn. These are to be pitied. Then there are those whose purpose it serves to deny ; and worst of all,

those who have tried, and altered their faith because they failed, those who, as the poet says, "fade away, and dying damn." To the credit of photographers there have been very few of these ; however, we have lately had an exhibition of one of them. A most enthusiastic defender of photography as an art of a few years ago, but who, perhaps, failed to prove it in his works, was politely asked to contribute to a recent exhibition, and is reported to have replied as follows—it is a lesson on the mutability of things to compare this letter with his former opinions : "I am fully persuaded that photography is not art, nor can be, and to encourage exhibitions is to lead a lot of vain people to waste their time in the practice of a useless and vain pursuit."

It has no effect with the prejudiced critic to point out, that if different minds using the same machines produced like results invariably, as machines are expected to do, any one of them who understood the machine ought to be able to turn out a series of masterpieces equal to the best that have ever been produced, always providing, of course, that one machine was as good, and as well brass bound and French polished as the other. Yet they continue to say—and this is one of the latest utterances of science : "The picture painted by the artist is a transcript of his own emotions, but a photograph is not a reflex of human emotions at all—unless, indeed, accidentally so—but a direct reproduction of nature, and only through science the offspring of man." We must be grateful to the writer for allowing us the accident.

I am quite ready to confess that up to a certain point, and in the hands of the ninety per cent. of the followers of the art who are not artists, the photograph is in the process ; but with the others the picture is in the man (as in painting, only in a less degree, and as far as the materials will allow). The process takes a very subordinate place, and is dominated by the taste, thought, and feeling of the artist, when an artist uses it with what may be fairly called emotional results. Who has not laughed with many of *Rejlander's* characteristic heads, or wept—yes, I have seen even that emotional result produced by a photograph (which was not an accident), and it is an important part of my argument that all these motions arose first in the mind of the photographer, and would never have been originated by the same models in the hands of another photographer.

Of all the attempts made to prove that photography was not an art, that which would have most force, if proved, would be that it howed no evidence of individuality ; but, on the other hand, if the possession of that quality were proved, it would be one of the strongest arguments in favour of the admission of photography to the brotherhood of art, for individuality, in its products, necessarily implies the operation of a directing mind behind the "soulless camera."

The latest of the many attempts to define the meaning of the word "art" is a very remarkable one. It is said to be, "The apparent disproportion between the means employed and the end obtained." And, as an illustration, the following explanation is given, at which, I think, many a practical photographer will smile.

"Admit, for argument's sake, that a photograph reproduces with a fidelity far beyond anything that the hand of man can attain to, it must still be allowed that the means used to attain this end are infinitely more complicated than the few hairs tied to a stick which the artist uses. Indeed, it might be argued that, if art is the apparent disproportion between means and end, photography is not art at all, but science. There is no art on the part of the lens when it produces its images ; it does so strictly in accordance with natural laws. The developer acts as thoughtlessly as any other chemical experiment, and these are the chief factors in every photograph. It is true you have one small part to play—you must have the art of exposing properly ; but even here a few shillings will purchase for you a machine to do even this. I do not admit art in development. Art in development is only called in when the exposure has been made without art, and, as I have already allowed art in exposure, I cannot allow it here again. With such an infinitesimal part of the picture the outcome of art, is it honest to call a photograph a work of art ?" Are we to understand from this singular piece of reasoning that painting is an art because the painter uses "a few hairs tied to a stick" ? and does the writer suppose that we claim photography as an art because of its fidelity—that heritage of the youngest amateur. This curious example of scientific knowledge of art is by Dr. J. K. Tulloch, of Dundee, and was written in the present century.

Some writers get confused between degree and kind. In an article in the *Magazine of Art*, a certain writer, who was once a photographer, endeavours to show that photography cannot become art, because its individuality is limited. That it is more limited than painting has always been admitted—we cannot go so far away from the truth as is the painter's privilege—but it is also admitted that all methods of art are more or less limited, and the amount of limitation is only a matter of degree, not of kind. The limitations add to the difficulty, but do not alter the status.

Let us run back a little and see if we can find a few workers whose

results are totally different from those of their contemporaries, and this invariably. One of the earliest photographers to show genuine art feeling in his work was Rejlander. He died sixteen or seventeen years ago; yet, among many thousands of photographs, it does not require much experience to recognise a Rejlander. There was nothing in the manipulation to distinguish them, except, perhaps, carelessness. It was the mind of the man that was visible, you recognise the man beyond the process. There are still those living who can say, on looking at a collection of old photographs, this is a Francis Bedford, a Dr. Dimond, a Fenton, a Delamotte, a Le Gray or Silvy, a Winfield or a Mrs. Cameron," certainly quite as accurately as an expert in painting would say, this is a Raphael, or Titian, or a Correggio. Then, what becomes of the machine argument?

I will now endeavour to put it another way. Photographs, as I have endeavoured to prove, show the mind of the producer—when he has a mind to show—and given two equally gifted photographers, as far as equality can be measured, the one could not produce even a colourable imitation of the work of the other. Neither could dismiss his individuality let him try how he may. Take two representative men, Rejlander and F. Bedford, neither of these accomplished photographers could have imitated the other. They had both original minds, and followed the bent of their genius, and their hands, as well as brains, showed in every picture.

Among the workers of the present day, I could point to dozens of well-known instances, but one or two must suffice. No man's work has been more imitated than that of M. Gale. In every exhibition, he is imitated in size, style, framing, and signature, yet an expert can decisively say of two pictures, This is the Gale, and this the imitation; he can even distinguish between the imitators, and say, This is a —, and this a —.

Then, in a very different style, there are the works of our much-respected President, than whom there is no one I would prefer to see occupy the honourable position which defective health compelled me to decline. Perhaps I am not a fit and proper judge of his pictures, but, without altering my opinion of what a photograph should be, I must confess that some of them have captured my admiration for their beauty and respect for other ways than my own when in good hands. Now, some have endeavoured to imitate Mr. Davison and some have renounced photography in despair, because they could only reach the eccentricity without touching the excellence. It is easy to put the image out of focus, but not so easy to make a picture by that means, and Mr. Davison makes pictures. It is easy to copy peculiarities, but not so easy to imitate valuable essentials.

While on the subject of our President, may I be permitted to add—for he is now in a public position and open to our shots—that, however straitened his views of the practice of photography as an art may have been at one time, his opinions have constitutionally broadened down, until now the key-note of his teaching is liberty for all.

We now come to another proof of individuality. It used to be the practice to insist on anonymity at exhibitions until after the judges had done their work; but this was given up when it became apparent that the judges usually recognised the work of the old hands, and the only nameless ones were new exhibitors. In America—at least, at the Convention Exhibition—the farce of the anonymous is still carried to such an extent that nobody seems to know, officially or otherwise, who the pictures are by until it is too late to be of any use to the exhibitors; and newspaper criticism has to be published without names. For, however the photographs may proclaim their authors, it seems to be etiquette to pretend not to know.

The difference between the works of some of our best photographers and those of the moderately successful can scarcely be due to a scientific cause, except, indeed, to a reversal of the generally

received idea; for, I think, if the truth were known, it would be found that the producers of the indifferent pictures had much more scientific knowledge than those who produce the most artistic pictures. I am acquainted with a great many of our photographers, but I do not know one of those to whom we are accustomed to look for the chief ornaments of our exhibitions who have any elaborate scientific knowledge. Indeed, their technical methods are so very simple as to seem quite elementary. They usually take a plate to the make of which they are accustomed, a simple pyro and ammonia developer, a handful of hypo, and a jug of water, and use them properly; and that is all. They do not bring science to bear even on the exposure, at the expense of "a few shillings." They get on without an actinometer. They feel from experience when their plate has had enough, and an actinometer, however perfect, would only confuse them. But, as they endeavour to put taste, thought, and feeling into their pictures, their works necessarily differ from those of the scientist, and the essence of their art is individuality.

My last word must be a word of caution. Be original, be unique if you can, but not out of harmony. Individuality goes wrong when it is out of harmony with its surroundings. Eccentricity is very easy, but it does not last. It is open to the meanest capacity, and is often assumed by it; but genius, to be useful, should consist of individuality, backed up by suitability to its environments.

Mr. CROOKE said he fully endorsed all that had been said by Mr. Robinson. Sometimes the means over-balanced the end, but all depended upon the mind of the individual who stood behind the camera. It was not every picture which should be out of focus; that depended upon the subject. He once had an assistant who had defective sight, and could not see to focus properly, yet his out-of-focus results were sometimes very fine. Small work such as miniatures should not be out of focus, and could not be compared with large work.

Miss C. WEED BARNES said she had lately been out photographing with Mr. H. P. Robinson, and in going home he had said to her, "Now, you've got some good

No. 5.]

"HAPPY CHILDHOOD."

[J. Tims.

pictures, don't spoil them in developing."

Dr. MITCHELL said that he thought the question was so clear and simple that the paper admitted of no argument.

Mr. C. H. BOTHAMLEY thoroughly agreed with the opinions expressed in the paper. No one could deny that there was individuality in photography. There were many paintings which no one could class as art, simply because they possessed no individuality.

THE PRESIDENT, closing the discussion, said there was not likely to be much difference of opinion as to individuality in photography. Anyone who had attended any of the large exhibitions knew that it was possible to at once pick out the work of certain individuals, although no indication of the worker's name was given on the print. A painter had said that if six painters sat down in the same spot one after the other they would get six different pictures; if six photographers were to do that you would get six prints exactly alike. He would at once deny this. Individuality could be shown throughout, in treatment of negative, etc. Sharp focussing throughout a picture in no case lends itself to artistic results; this was his view, but he claimed that all were at liberty to do as they liked. He considered that both in large and small the very broadest treatment could be used if the printing process was suitable.

The demand for platinum for industrial purposes is relatively restricted, as it only dates from the last twelve or fifteen years. It is largely used for electric lighting and dynamo conductors, and considerable quantities of platinum are now employed in chemical and other factories.

## PHOTOGRAPHY IN RELATION TO PAINTING.

By ARTHUR BURCHETT.

In commencing this paper on "Photography in Relation to Painting," I feel that I cannot do better than give the definition of both painting and photography.

Painting is a representation of objects on a flat surface, painted by the hand by means of brush, pencil, or other tool being under the will of the artist, unrestricted in fancy, subject, colour, form, place, or period.

Photography is a representation of objects on a flat surface, restricted to the absolute reality of form present, as rendered by the lens on the sensitive plate in the camera, being only under the control of the photographer in development and in choice of subject, form, place, focus, and length of exposure, and in some few cases light and shade.

Such being the definitions of painting and photography, we can now see how very limited are our resources in photography, compared with painting, for producing a picture that shall have qualities that give it an art value, for it is not a mere transcript of nature that we require, but a picture containing some sentiment or idea that shall give pleasure to those who see it, and in nature there is in both figure and landscape an endless wealth of beauty that we can

No. 6.]

"THE MORNING BATH."

[W. Herbert.

render, if we see nature with the knowledge of what the camera will do and what it will not do.

Photography being limited to reproducing the objects present without colour (which in painting is often its chief charm), we must, therefore, find out how near photography approaches painting by comparing reproductions of paintings with the work of the lens. Unfortunately, photography is severely handicapped by the inability of the sensitive plate to render the true tone value of all colours, and this inability adds very much to the difficulty we have in judging Nature as she is represented in the photograph and in painting; but even with this defect the result in photography is very close to the true rendering of Nature, and will be even more so in time as photography advances. I need not point out the defects of photography with regard to rendering colour into black and white, for we all know them. In painting, certain colours have a different tone value to some artists than to others, and when their pictures are rendered into black and white, we fail to recognise the likeness of effect to that of the painting.

Both in photography and painting we have to consider in the construction of the picture, the possibilities of its being a success, its story, composition, light and shade, and all the various items that make its being. A painting or photograph must have some reason for existing, some object or story, and this must be the one thing that all else is to be subservient to. In a picture the artist tries all he can do to keep your attention fixed on his principal figure or object, and to do this keeps all his, what we call, "focus" on it, and all else is kept down both in tone and sharpness, so that the eye shall not wander away and become confused by the surroundings. Many pictures and photographs are spoilt by the want of concentration of interest, simply by forgetting this simple rule, in painting by over-elaboration of unimportant objects, brilliant colour or strength which kills the principal object in the picture; in photography by microscopic focus, which puts everything on an equality with the principal object, accentuating things that are unseen by the eye, for the eye sees the thing that is, not what it is made of; a tree is made of many leaves, branches, etc., but the eye sees them as a mass of foliage, not as individual items.

Many pictures are spoilt by want of contrast of light and shade, for it is a well-known rule in art (and art applies to photography as much as painting), that except in exceptional circumstances there shall be no accessory object lighter than the principal object of the picture, or if that is a dark, darker than this object. In this was the secret of the great success of the old Flemish artists, Rubens, Vandyke, Rembrandt, etc. Both photographers and artists cannot do better than carefully study the way in which these masters have managed the light and shade, both in portraiture, figure, and landscape.

The next thing to consider is the composition or arrangement of the figures or objects that constitute the picture or photograph. In painting this is comparatively easy, as the artist can place his figures where he pleases, and use any kind of composition. But the photographer is entirely limited to a more or less equal plane of focus, owing to the distortion the lens gives in figure subjects, for what is simple foreshortening in painting often becomes absolute distortion in photography.

Composition not only applies to the arrangement of the figures but also to the light and shade, which must be so managed that it gives value to the lines of the figures, and in figure and landscape pictures so combine them that they become as a whole. With pure landscape photography composition is impossible, as you cannot arrange your objects; you can only select a view, and can only use the knowledge of composition to help you to choose the best view. In landscape and figure pictures very much can be done in photography, but you are limited to simple arrangement in a selected landscape, which has to be taken just as it is, and which in painting would be so altered and arranged that it would carry the lines of the composition in harmony with the figures.

Light and shade in landscape, which are so important in painting, are quite as important in photography; but here again we cannot arrange like the artist, but are quite dependent upon the effect at the time of exposure, which can sometimes be chosen. It is a very great misfortune that photography will not render the true effect of cloud and sky combined with landscape, for until this is possible we must depend upon the sky from another negative, which more often than not is entirely unsuited to the landscape, and also is, as a rule, printed far too heavy.

In painting, besides the great charm of colour, the artist has one which is perhaps greater, that is, "Ideality," or the rendering of the image of the mind as opposed to the reality. Idealism in painting often merges into mannerism. There are many living instances of this, the weary repetitions of the same form and the same effect. In photography the danger of mannerism is greater, as if we use the same stop to the same lens and the same printing method, our photographs must necessarily look more or less alike, only the difference of form. I suppose it will always be so, at least with the majority of workers who only have one lens. Painting is very much like handwriting, one can recognise the author, but photography changes in character with every different kind of lens, so that it ought to be possible to escape from the more glaring faults of mannerism.

Impressionism must not be confounded with idealism, for impressionism is the rendering of the way the objects or scene appeal to you, how you see it, whereas idealism is the correcting or altering nature to suit what you consider true beauty.

Impressionism in photography is not only possible to a very large extent, but the results are very beautiful, and *do* depend in a very large measure on the artistic aptitude of the photographer and the knowledge of his lens, and though, to those who are unable to see the beauties of nature (and they are legion), it may appear entirely chance work, yet those who are using knowledge both of nature and photography know that the results are precisely those that were aimed at.

And now we come to what is considered to be the great strength

of photography, its imitation of form. In painting it is often colour that expresses form, such as grass, sand, and many other things. There the colour tells what it is, and the mind is satisfied, but in photography, unless there is a *sufficient* indication of form, the representation is vague and leaves the mind wondering and unsatisfied; it is therefore necessary to the proper understanding of a scene or object that the definition of form shall be such that the objects are recognisable, but how far it should be carried is entirely a matter of individual feeling, for as in the case of idealism, the perception of form is in the mind, to one person form is soft and without line, to another the feeling of form is so strong that he can only express himself by sharp outlines, it is only a matter of thought, for in nature there are no outlines. The impression of nature is to me a soft blending of colour and tones quite unlike the rendering given by what is termed "a nice sharp photo." One of the great difficulties both painters and photographers have, is the introduction of figures into landscape so that they shall not intrude or attract the eye from the motif of the picture. As a rule, we find in the best landscape pictures, that if a figure is introduced it is placed in the middle distance, and is

neous photograph of the movement of a figure the chances are that he has never even dreamt of that representation being what it is intended to represent. The very fact of its being a *perfectly* arrested action takes away all sense of movement and makes it only a pose. In landscape the expression of movement cannot be expressed by a perfectly sharp image. How often one hears the remark, "This is not good, as the trees have moved." Yet to an artist it is often the best quality that photography possesses. Turner, the great master of movement, always got the effect of wind in his trees, waves, and sky by indistinctness of detail.

Sea and sky in photography are often perfectly representatives of movement. One need only see one of Dresser's seascapes to acknowledge this, but there are many other photographers who only give the arrested motion, the stillness of death, for it has the form but not the breath of life.

The imitation of nature should be in photography what artists have endeavoured in all ages to paint—that is the life of nature not as a still, sharp microscopic image (for the time is past when we were content with seeing nature under this false light), but as a representation of life as seen by the eye; for what is false to the eye cannot appeal to the mind. It may be a perfect photograph, as far as exposure, development, and printing can make it, but unless it has that something which truly represents the life of nature, it is worthless in an artist's sense.

Mr. T. C. HEPPWORTH said that the one noticeable point about this paper was the absence of abuse. There was at least one artist who could appreciate photography, probably because he was at once a capable photographer and artist.

Dr. MITCHELL, in referring to the photographing of movement, paid that one physical fact often overlooked was the persistence of vision, which lasted from  $\frac{1}{10}$  to  $\frac{1}{50}$  of a second. Often a quick exposure represented a moving object as a crystallized thing. The best sea pieces were taken with a slow shutter, and the same might be said of animals. The movement of the small muscles was lost by the eye, and in his well-known pictures Prof. Muybridge showed positions which were not recognisable to the human eye.

Mr. STURMEY said that there was no reason why artists should not select those from Muybridge's studies which were at the same time artistic and truthful.

Mr. F. P. CEMBRANO said that both a photograph and a painting must have a reason for existence; there must be one principal object. Often clouds were introduced which did not suit the landscape, and the best effects were obtained by printing clouds from a separate negative, as the clouds which might be present at the time the original negative was taken might not be suitable from an artistic point of view.

Miss C. WEED BARNES said that before she used the camera she had started painting, and it had been early impressed on her that she should note the highest light and deepest black, and that everything should be subordinate to that, a precept she endeavoured to carry out in photography.

THE PRESIDENT said that Mr. Burchett was at once an artist and a photographer, that he had lost his colour sight and had taken up photography, and that although fortunately he had recovered his colour sight, he had not given up photography. The author had spoken of the difficulty of photography to render the true tone value of colour, but he drew attention to the orthochromatic process; Mr. Burchett had worked out and patented a method of getting over the difficulty by using coloured glasses, and Mr. Burchett had kindly placed some results at his disposal for show.

Mr. J. J. Elliot, of Laygate Terrace, South Shields, has opened up a photographic department for the sale of apparatus, etc., and offers the use of his dark-room free to visitors.

**Platinum.**—During the last twelve years the annual production of platinum has averaged about 3,194 kilogrammes, of which half has been derived from the beds in the north of the Ural mountains belonging either to the State or to private persons. Throughout the whole world only about 3,270 kilogrammes of platinum are annually used, but it is anticipated that this amount will soon be considerably increased, and it is stated that the platinum beds of Bisserski can alone supply the total quantity required for the consumption of the world. When the demand for platinum was insignificant and the price very low, the gold miners who found platinum while seeking gold, frequently, it is stated, used the former instead of lead, as shot for firing at wild birds. It is only since the demand as increased that greater attention has been paid to this metal. All the platinum extracted from the Ural mountains, after having paid a tax of 3 per cent. in kind, is sent as raw ore to St. Petersburg for treatment and shipment to foreign markets.—*Journ. Soc. Arts.*

TAKEN WITH WORMALD'S "PHOTOMNIBUS."

used more to serve as a known size to give grandeur to the landscape. Turner was a master at this, and though he defied this method in some of his pictures by placing the figures in the immediate foreground, yet he did it so well that they appear away from where the spectator stands, and therefore practically in what is the middle distance. Of late years it has become more the fashion to introduce figures in the foreground, so as to give a title to the picture, but it is very difficult to do so without sacrificing the landscape to the figures. Of course, these remarks do not apply in the case of what are called "figure and landscape subjects," for there the figure is the important object and the landscape only accessory.

I am afraid that my paper will not be considered complete unless I make a few remarks on motion, as rendered by the camera and by the artist. I know that it is dangerous ground to tread upon, but I must needs venture. In the expression of movement in painting, the artist does not endeavour, like the photographer, to obtain a perfectly still look or an action that he cannot see, but such an action that shall express the characteristics of the movement he wishes to represent, whether it be running, leaping, falling, etc., and obtains that look of movement, not only by the position of the figure, but also by means of flying drapery. Now, in pictures by many of the great masters, this drapery is painted in indistinct folds, *purposely* to give the effect of movement. There is a very fine instance in the National Gallery, London, "St. George and the Dragon" (by Tintoretto), perhaps the finest example of movement ever painted. To say that movement must be expressed by moved ment expresses what I wish you to understand. In this picture not only do the figures seem to be moving, but the drapery vibrates; but still it has not the same kind of look that photography gives of the blur of movement, but is of a character that I am afraid photography can never imitate. Another instance of the rendering of movement is Vandyke's drawings of the condemned being cast into hell. The mass of humanity seem to fall headlong. The effect of movement is indescribably true. When an artist looks at an instanta-

## "Amateur Photographer" Competitions.

## MONTHLY COMPETITIONS.

DATES FOR RECEIVING PHOTOGRAPHS.

SUBJECT, Inland Scenery, with or without Figures, October 24.

SUBJECT, Sea Pieces or River Scenery, August 22, November 21.

SUBJECT, Portraiture and Figure Study, September 19, December 19.

## CONDITIONS.

1. Only one print to be sent in to each competition. The negative of the prize pictures shall be at the service of the proprietors. All the prints entered for competitions shall become the property of the proprietors.
2. The work must be entirely that of an amateur photographer—exposure, development, retouching, printing, and toning. Mounting by the competitor is not compulsory.
3. Photographs may be printed by any process or on any paper, but must not be printed on opal or mounted in optical contact on glass, or from an enlarged negative.
4. All prints must be sent in not later than the date given. They will all be acknowledged or criticised in the AMATEUR PHOTOGRAPHER Illustrated Monthly Supplement, the prize photographs and others being reproduced.
5. No name must appear on the print, but the title must be legibly written on the front of the mount, and the entry form duly filled up and enclosed.
6. Open to ladies or gentlemen; one print only to be sent in.
7. All prizes will be in the form of medals from the AMATEUR PHOTOGRAPHER'S dies (small series). No prize-winner will be allowed to compete again for a Medal of the same value as that awarded him. The AMATEUR PHOTOGRAPHER Monthly Competitions are for the encouragement of beginners and those who have never entered a competition or exhibited their work.
8. Prizes—Silver and Bronze Medal, with ribbon and clasp.

## THE 1892 ANNUAL LANTERN SLIDE COMPETITION.

Entries will close on September 30th, and the following are the classes and prizes:—

## CLASS I. LANDSCAPE, SEASCAPE, AND RIVER SCENERY, with or without figures.

First Prize	Gold Medal
Second Prize	Silver Medal
Third Prize	Bronze Medal

## CLASS II. PORTRAITURE AND FIGURE STUDIES.

First Prize	Gold Medal
Second Prize	Silver Medal
Third Prize	Bronze Medal

## CLASS III. ARCHITECTURE, interior or exterior.

First Prize	...	...	...	...	Gold Medal
Second Prize	...	...	...	...	Silver Medal
Third Prize	...	...	...	...	Bronze Medal

## CLASS IV. INSTANTANEOUS WORK, limited to slides from 5 by 4 negatives and under.

First Prize	...	...	...	...	Gold Medal
Second Prize	...	...	...	...	Silver Medal
Third Prize	...	...	...	...	Bronze Medal

Certificates will also be placed at the disposal of the judges.

Entry forms and conditions, etc., may be obtained on forwarding stamped directed envelope.

## "HOLIDAYS WITH THE CAMERA" 1892, COMPETITION.

## RULES AND CONDITIONS.

PRIZES:—Gold, Silver, and Bronze Medals, and Certificates, with special prizes of "Niepce" or progressive medals for past prize-winners.

## "OPTIMUS" 100 GUINEA COMPETITION.

MESSRS. PERKEN, SON, AND RAYMENT, of 99, Hatton Garden, E.C., have made us a very handsome offer, which we have unhesitatingly accepted on behalf of our readers. They will place at our disposal 100 guineas worth of apparatus, manufactured by them, on the following conditions:—

A. That the lenses used should be of the well-known "Optimus" brand, and have the trade mark and name engraved on the mount.

B. All the prints sent in to this competition shall become the property of Messrs. Perken, Son, and Rayment. The negatives of the prize prints shall also become their property.

The following are the classes and rules:—

1. Every prize winner shall be required to make an affidavit that his negative has been produced by the aid of an "Optimus" lens within the given period, and shall produce the lens if called upon.

2. That every print must be from a negative produced since January 1st, 1892.

3. The artistic trimming of prints shall be allowed, but in all cases the full size of the negative must be stated on the face of mount and entry form.

PRIZES FOR THE "OPTIMUS" 100 GUINEA COMPETITION.

SUBJECTS.—All photographs are eligible that have been taken during the "holidays," but must be landscape or sea pieces with or without figures, views of towns, photographs of cathedrals, churches, public buildings, etc., but not portraiture, figure study, or pictures which could be classed as "Photography at Home." The prize pictures will become the property of the Proprietors of the "AMATEUR PHOTOGRAPHER;" other photographs will be returned if stamps be enclosed to cover postage.

NUMBER.—Not more than twelve or less than six prints are to be sent in. They must all be mounted and numbered to correspond with the numbers in the MS. They will be judged upon their merits as a whole.

DESCRIPTIVE NOTES.—Each competitor must contribute a short account of his holiday, to be not less than 500 or more than 1,000 words.

DATE.—All photographs must be received on or before the 31st December, 1892.

4. Enlargements or prints from enlarged negatives will not be admissible.

5. The whole work must be done solely by the competitor.

6. All prints shall be mounted, and bear on the face of the mount in the middle, half an inch below the base of the picture, a written or printed title, and on the back a *nom de plume*. The mount must not project more than one-third of the picture on each side; for example, the mount for a print measuring  $7\frac{1}{2}$  by 5 must not measure more than  $12\frac{1}{2}$  by  $8\frac{1}{2}$  in.

7. With each print must be enclosed an envelope bearing on the outside the *nom de plume*, and inside an entry form duly filled up, bearing competitor's name and address.

8. All prints and entry forms must be received by October 31st, and must be marked outside "Optimus' Competition."

## CLASSES.

1. Landscape, with and without figure. Sub-class A, 7 by 5 and under; sub-class B,  $8\frac{1}{2}$  by  $6\frac{1}{2}$  and over.

2. Seascape. Subclass A, 7 by 5 and under; subclass B,  $8\frac{1}{2}$  by  $6\frac{1}{2}$  and over.

3. Portraiture and figure study. Subclass A, 7 by 5 and under; subclass B,  $8\frac{1}{2}$  by  $6\frac{1}{2}$  and over.

4. Instantaneous work, including also hand-camera work, limited to 5 by 4 and under.

#### PRIZES.

Apparatus to the value of:—

Class 1.—Subclass A, prize £15; subclass B, £15.

Class 2.—Subclass A, prize, £15; subclass B, £15.

Class 3.—Subclass A, prize £15; subclass B, £15.

Class 4.—First prize, £15.

The competition is open to all—amateurs and professionals.

Latest date—October 31st.

## Photographic Procedure.

By E. J. WALL,

Author of the "Dictionary of Photography."

### SECTION V.

#### THE SENSITIVE MEDIUM AND ITS SUPPORT.

(Continued from page 6.)

*Sensitometre Rationel.*—M. Goderus has introduced a modification of the above sensitometer, as shown in the following figure, in which two narrow slips of the plates to

FIG. 129.

be tested are placed in the sensitometer and exposed simultaneously to the same light, when, as in the previously described methods, the relative sensitiveness is determined by the highest number visible.

We have now briefly considered the leading methods adopted or suggested for determining the sensitiveness of plates, but it would not be out of place to include here the method adopted by Messrs. Hurter and Driffield and Mr. Alfred Watkins, as many use the tables of speeds determined by them. Messrs. Hurter and Driffield thus explain their system:—

"It has been customary hitherto to compare plates of different rapidities with the collodion wet plate as a standard, and modern dry plates are spoken of as being so many times as sensitive as wet plates. Apart from the fact that the majority of photographers of the present day have no experience whatever of wet plates, that these alleged speeds are otherwise most arbitrary and unreliable, and that wet plates themselves vary in speed, the system of referring one plate to another as standard is bad. We feel strongly that one of the most pressing photographic requirements of the day is the adoption of a scientific unit of speed, which will admit of an accurate comparison of the rapidity of different plates. We must all feel what a boon it would be if plate-makers were in a position to state definitely on each packet the speed of the plates it contained. We know this is attempted, in a manner, by referring, in some cases, to Warnerke's sensitometer numbers; but this is a most crude and unsatisfactory method of judging the speed of the plates. You may purchase to-day a plate by a certain maker and with a certain label, and you may find it to be a certain speed, but this is no criterion that if you purchase another sample of what professes to be the same plate, in a few months' time, you will find it of the same speed. I could name a certain commercial plate which some months ago had an actinograph speed of 7, while the last packets I procured of the same plate had a speed of 18, or were nearly three times as rapid. In another case I worked with some plates the speed of which was 35; all at once, without the slightest notification of alteration, the speed dropped to 20, or in other words, the plates were about half their original speed. Till plate-makers therefore are provided with

and adopt some methods of estimating the speed of their plates, the best plan for photographers who wish to save annoyance and expense is to purchase a large stock of plates at the same time, with a guarantee from the maker that they are all made from the same batch of emulsion.

"Now we have attempted to remedy this defect in the nomenclature and comparison of plates, by choosing as measure for the speed of the plates, the length of time it takes to produce a definite result upon the plate. Let us consider, for a moment, a landscape negative in which there is a considerable expanse of sky, and say of green pasture in the foreground. We all know that in the case of over-exposure, the density of the grass will come more or less nearly up to that of the sky, and a flat, uninteresting negative will result. On the other hand, in the case of under exposure, in the effort to force detail in the grass, the sky will become extremely dense while the grass may be represented by almost bare glass. Now we cannot fix upon a definite density for the sky alone, because almost any density is compatible with either under or over-exposure, but in the case of a rightly exposed negative, be it either generally thin or dense, there is a definite ratio of density between the sky and the grass, which we find to be about as 1.7 is to 1. We have, therefore, decided to take the exposure required to produce this definite ratio of density, under special conditions of light and lens, as a measure of the speed of the plate. Hence we call the speed of that plate 1 which produces this necessary ratio of density between sky and foreground in one second with one degree of light, the intensity of the light reaching the plate being equal to that sent out by the object; and we call that plate speed one hundred which produces the same result, under the same circumstances, in the 1-100th part of a second. It will be obvious that it is impossible, in practice, to comply with the above-named conditions, and the speed has therefore to be calculated from results obtained under practical conditions. An example will best show how this calculation is made. We will assume that a negative with the requisite ratio of density was obtained on June the 8th, at 11 a.m., in the brightest possible light. The light at this time, in our latitude, would be 85 actinograph degrees. The lens used was a rapid rectilinear working at intensity  $f/32$ , and the exposure given was  $2\frac{1}{2}$  seconds. With such a lens and stop, the light reaching the plate is  $32^2$  or 1,024 times less in intensity than that emitted by the object. As I said before, however, the lens absorbs and reflects a certain proportion of this light, and the amount, in this instance, which actually reaches the plate consequently becomes 1,351 times less than the light reflected by the object. This figure 1,351 we divide by 85, the degrees of light; and by  $2\frac{1}{2}$ , the time of exposure in seconds; and the result, viz., 6.3, is the speed of the plate."

Mr. Watkins, I believe, exposes plates in the camera to one uniform colour—i.e., to a colour which he has found to be as closely as possible to the prevailing tone of a landscape and from the developed negatives estimates the speed.

Many other methods have been suggested for testing the sensitiveness of plates, such as exposing a plate in a camera to the sky on a cloudless night, and then finding the lowest magnitude star, the image of which had impressed the film, a suggestion which does not strike one as very practicable. Another plan suggested, and one often used by commercial firms, I believe, is the photographing of a white bust against black or dark drapery, and then comparing the results obtained.

It is to be hoped that sooner or later we may have a committee of capable men which shall be able to fix upon some test which may be universally adopted by plate makers, for determining that much-vexed question, the sensitiveness of a dry plate.

*Paper and Film Supports.*—Hitherto we have been considering merely the emulsion, and tacitly admitting glass as the only support, but it would not be well to dismiss this section without a brief reference to other supports than glass; and, considering the enormous and ever increasing strides lighter supports are now making, a brief historical retrospect may not come amiss.

In the early part of this century Wedgwood and Davy used paper and white leather impregnated with silver salts to obtain images by the action of light. In 1834 Fox Talbot also used paper impregnated with chloride of silver, and in 1838 he tried iodide of silver. In 1839 Fox Talbot accidentally discovered the fact that the latent or invisible

image could be developed with gallic acid. Negatives were thus produced, and although the grain of the paper was apparent, waxing the paper partly obviated this fault. Then in 1871 the late W. Woodbury suggested a paper support, rendered transparent by means of certain resins, and he also suggested using the paper in bands or rolls. In 1876 Warnerke used collodion or bromide emulsion on paper, and Messrs. Morgan and Kidd for years made such paper commercially, some of which the writer still has unexposed, and also negatives made on it. Pumphery introduced films, and Vergara a film of chromated gelatine rendered insoluble by the action of light.

The Eastman Company then introduced what they called a stripping film, which consisted of a film of bromide emulsion, coated on an insoluble film of gelatine, with paper as a support. Fry and Co. also introduced something of the same kind.

The greatest advance made, however, was undoubtedly the introduction of celluloid, which is prepared in a particular manner from pyroxylin; and the Eastman Company and Carbutt were again to the fore. The former manufacturers, however, not content with the cut film, experimented till they were able to turn out the film in lengths sufficient for from 24 to 100 exposures, the bands or rolls of films being used in a special form of dark slide called a roll-holder or roller-slide. Within the last few months cut films have also been further improved, in that they are now manufactured by Fitch and Edwards in a perfectly flat form with no tendency to buckling or cockling.

It may as well be stated here, once for all, that in the following articles, wherever plates are spoken of, films are also meant, and that the treatment of films, except in particular cases, in no way differs from that of glass plates. They are, in many cases where the manufacturers make both plates and films, coated with exactly the same emulsion, and no one need be afraid of using them for fear of having something new and hard to learn.

(To be continued.)

## Reviews.

*Photographic Reproduction Processes.* By P. C. Duchochois. Edited by E. J. Wall. Hampton, Judd and Co., 13, Cursitor Street, E.C. Price 2s. 6d.

This work, which is an English edition of that published in America, will form a very useful addition to our libraries, treating as it does of all the printing processes without silver, such as cyanotype, cyanofer, uranium, platinotype, aniline, primuline, and other processes. Whilst many of the processes are but little known, it is convenient to have in a collected form the leading features of the same, and the work will be welcomed by all who are willing to stray from the beaten tracks and experiment for themselves.

*Formules Photographiques.* By Abel Buguet. Published by Société d'Éditions Scientifiques, 4, Rue Antoine Dubois, Paris. Price 5 fr.

The photographer who has surmounted all elementary difficulties often desires to experiment with different methods of working, solutions, etc., and this little work will be found useful, comprising as it does all the latest formulæ for the various processes extant.

A lunar photograph taken by Professor Holden, of California, has just been enlarged by Dr. Weinek, of the Prague Observatory to the size of twenty times the original. It shows the surface fully nine feet in diameter, the most remarkable feature about it being the river-like lines on it. These markings are many and unlike in appearance, but what they are composed of it is hard to say. For, as there is no water in the moon, streams they cannot be. But of late such a multiplicity of questions have been raised in reference to our satellite that a new and systematic investigation of that orb is requisite.

## Printing in Platinum.\*

By M. W. THOMPSTONE.

THE first who really appears to have endeavoured to obtain a paper-printing process by the means of platinum salts seems to be Robert Hunt, but as he was unable to obtain a workable one it was allowed to drop till the year 1874, when Willis succeeded in producing the first platinum process that could be relied on, and which, with very slight alteration, is the hot-bath process of the present day.

Willis's process is undoubtedly a toning one, inasmuch that platinum replaces iron, in the same manner as gold replaces silver in the albumenised and gelatino-chloride processes.

That ferric were altered to ferrous salts by the action of light was known early on in photography, for Sir John Herschell prepared paper by means of the iron salts, and replaced them after printing with gold.

Willis further improved it by substituting platinum for gold, and in discovering that a solution of potassium oxalate caused a precipitate, also the advantage of the platinous over the platinic salts.

The paper is coated with a mixture composed of ferric oxalate and platinous chloride, but after it has been exposed to light we have present both ferric and ferrous salts in union with the platinum one, but not in a chemical state.

The ferrous salts have only the power of reducing the platinum in the presence of potassium oxalate, but the ferric has no action on the platinum when so treated, so the following reaction takes place: when the print is immersed in the potassium oxalate, the ferrous oxalate formed dissolves, and in so doing throws down the platinum in a metallic state in proportion as it has been acted on by light when exposed under the negative, but where he light has not been able to penetrate the ferric salt remains unaltered, and no reduction of the platinum takes place.

The next thing is to remove the ferric salt, which is done by immersing it in several changes of hydrochloric acid, diluted in the proportion of one part of acid to sixty parts of water.

In the cold-bath process the platinum is added to the developer instead of being contained in the paper as in the hot-bath.

Recently the Platinotype Company have introduced a new paper similar to the hot-bath, but the developer is used cold. This is the process I intend showing you to-night.

The paper having been exposed in the ordinary way till the details can be distinguished, when it is placed in the developer, viz., 1 lb. of potassium oxalate, to 60 oz. of water, the image soon makes its appearance and darkens rapidly, but is quite under control. As soon as it has arrived at the required density it is placed in the first clearing bath and left for about five minutes, then in a second and a third till there is no trace of yellowness in the last bath, washed for about half an hour, dried and mounted in the ordinary way.

I find that I get better results with a thin but vigorous negative than I do with denser ones, and as for results I don't think those obtained by means of silver can compare with the platinum for their velvety softness and beauty of tone.

Herr Rudolf Mayer Nachf, of Munsterstrasse, next the Munster, Friburg, Baden, has opened a dark-room for the free use of all amateurs and tourists who may be travelling near there.

Mr. Paul Lange has again revisited Norway this year, and covered new ground, and has now a lecture ready for delivery. His previous lectures on "Iceland" and "Norway" are well known, and well worth hearing and seeing, illustrated as they are by lantern-slides.

Newcastle-on-Tyne.—On the 14th inst. a party of sixteen members had an outdoor meeting down the Tyne. The party journeyed by the one o'clock boat from Newcastle Quayside to North Shields, several exposures being made at the shipping on the way down. On arrival at the Fish Quay the number of cameras on the scene caused a good deal of excitement amongst the fisherfolk, several being very anxious to be photographed. After exposing a number of plates on the various groups, the party crossed the river to South Shields, when Mr. William Parry, who ably acted as leader, photographed the members. After tea Mr. Parry kindly showed them over his studios and printing rooms. A most enjoyable day was spent, and the weather was all that could be desired.

\* Read before the South Manchester Photographic Society.

## Societies' Meetings.

**Ashton-under-Lyne.**—On the 21st inst., Mr. Wm. Chadwick reporting on the Society's outing to Broadbottom, July 16th, stated that, owing to the inclement state of the weather, only eighteen members put in an appearance, and, considering the rain only ceased a few minutes before starting, he thought it a good muster. The party left Guide Bridge station at 2.18 p.m., arriving at their destination about 3 o'clock, no time being lost in getting to work, but the strong wind which prevailed during the afternoon prevented many good pictures of river scenery being secured; in fact, the wind was blowing a perfect gale, and it was impossible to get the foliage in anything but a blurred mass. Mr. Chadwick gave a Darlot compound focussing glass for the best picture taken on the "out." The prints were judged at the Society's rooms, 21st inst., by Mr. Tom Heywood (late President, Oldham Photographic Society), the prize being awarded to Mr. W. H. Pleasants. Mr. Heywood showed in one or two cases how really good pictures might have been made by cutting the prints down instead of sending them in the full size. During the evening samples of the celebrated Paget Prize plates were distributed amongst the members, the same firm presenting the Society with a framed enlargement showing the excellent results which have been obtained on their plates. Members are reminded of the ramble to Crowden, July 30th. Leader, Mr. Charles Lord.

**Brixton and Clapham.**—An ordinary meeting was held on the 19th inst., Dr. Reynolds, President, in the chair. Some interesting questions were taken from the box and discussed, one of them being, "Is it necessary that the axis of the lens should be at right angles to the plate?" Upon this opinion was fairly evenly divided, but apparently the majority considered that it was not absolutely necessary. Another question which is of interest at this season of the year was, "Is it advisable for sea pictures to use a quick plate and a small stop, or a slow plate and a large stop?" and the feeling of the meeting seemed to favour the latter view. A third question was, "Does any member find the Ilford P.O.P. paper tone rather slowly?" This was answered in the affirmative. Subsequently the club lantern was used to throw upon the screen some slides contributed by Mr. J. Goldby and the Hon. Sec. The Paget Plate Company kindly sent some samples of their Prize plates for distribution amongst the members. The following works were kindly presented to the library: by the Britannia Works Co., "Ilford Manual of Photography," and by the Fry Manufacturing Co., "Bromide Enlarging."

**Great Yarmouth.**—The members of the above club started on the 19th inst. for a cruise on the Norfolk Broads in the yacht *Twilight*, kindly lent to them by Mr. Bly. They left the Vauxhall Station, Great Yarmouth, by the 7.40 train for Acle, where the yacht had been left overnight, thus avoiding the delay of the sail through this part of the river Bure, which is not very interesting, and which does not offer many opportunities of a snap-shot. All the provisions and gear having been got on board, breakfast was served and a start made at ten a.m. Favoured by a fair wind the yacht glided along, and the mouth of the Thurn was soon reached. A sudden bend in the river here necessitated a beat to windward, so two of the members volunteered to row the dinghy, and thus ease the yacht. The celebrated old ruin of St. Benet's Abbey was passed, and snap-shots made *en passant*, also the entrance to Ranworth Broad, soon after which the mouth of the river Ant was reached, and here again a fair wind was obtained, which soon brought the yacht to the bridge at Ludham. Here the mast had to be lowered, so that the yacht might pass under the rather narrow arch of the bridge. Sail was set again, and a very pleasant trip made up this interesting but rather narrow river with its sharp turns and picturesque scenery. At length Barton Broad was reached, and, after a sail round, the yacht was brought up alongside the bank, just inside the mouth of the river Ant, where some very picturesque cottages, farm-houses, and the picturesque old church afforded an opportunity for several shots. At 1.30 dinner was served and thoroughly enjoyed, for a sail on these waters is very conducive to a good appetite. Unfortunately, rain began during dinner, and continued so heavily that the yacht was started for Stalham. A wet run was made over Barton Broad and into the Stalham Dyke, where the river is lined on both sides with lovely white lilies and bulrushes. The yacht was safely brought up at Stalham Staith, and two of the members left by train for Yarmouth. After a very wet and stormy night, Wednesday morning turned out more favourable, so after a good breakfast a start was made in the dinghy and several fine views taken. Wednesday night was less windy, and with two comfortable cabins and a nice warm fire the members passed a pleasant evening, and obtained a comfortable night's rest. Next morning the yacht was joined again by other members, and a pleasant day's sail was made back through Stalham Dyke, and over Barton Broad to the Thurn river. Here a pleasant trip was made on to Womack Broad, where the quaint views to be obtained offered a good field for the cameras. Fine weather

prevailed, and, after a pleasant trip, Potter Heigham Bridge was reached in the evening, and some of the members returned to Yarmouth by train. On Friday a start was made again, and the trip to Wroxham begun. The scenery past Horning town and Salhouse, Wroxham Broad up to Wroxham Bridge is so picturesque that many favourite spots were photographed, and the yacht was at length left at Wroxham, from whence the members returned home, after a most pleasant and profitable cruise on these delightful and picturesque waterways.

**Hackney.**—Meeting held on 19th inst., Mr. C. F. Hodges in the chair. Mr. Nunn showed prints taken of the animals at the Zoo, and a plaster mould he had photographed—gave six seconds with rapid plate, *f*/16, by gaslight. A discussion on sticking (when using gelatino-chloride paper) was then taken up. Mr. Reynolds advised the use of a glass, which was first heated, and then putting on wax and rubbing with flannel until very little wax was left. The chairman had used ebonite, and as an emergency the papier-maché trays now so commonly used. Mr. Dean said he thought if alum were used before squeezegeeing [to plate prints would not stick. Mr. Poulson used ferrotype plate. The Chairman observed that people as a rule were too much in a hurry, and tried to peel them off before thoroughly dry. Mr. Dean showed a print from a mayfly which he had shut in a book and then photographed. The edges were stained of the negative, which had been developed with ferrous oxalate. Mr. Beckett observed that he would put the negative direct into the fixing-bath. Mr. Hensler asked how to stop up holes in negatives. Mr. Foulkes-Wirks said, if thin negatives, would varnish, and then use the pencil. Mr. Beckett said he would match the colour of the negative—with colour. The chairman said he once lost part of a negative through film getting torn. Mr. Foulkes-Wirks said he would advise under such conditions that a print be taken in platinum and then filling in with pencil, and then a reproduction taken. A question was then asked as to a good combined toning and fixing bath for Aristotype prints. The Eastman last formula was recommended. Mr. Sodeau observed that corks in these bottles of solution was not to be recommended, as the solution would not keep so well. A question was asked on intensifying with quinol. Mr. Beckett said he used cyanide of silver as fixing—if not thoroughly washed, stains would result. Mr. Winks said when printing for platinum toning it would be best to print darker than usual. Mr. Hensler then asked how to use saturated solution of hypo. Mr. Sodeau said, take 1 oz. of solution and 1 oz. of water. Dr. Colquhoun was nominated for membership. Mr. B. Foulkes-Wirks then gave a paper on "Dodges." Among the hints given were how to back plates, how to reduce with ordinary camera, flatten silver prints (by passing a paper-knife over the back) to cure pinholes, transparent spots (the former with retouching medium and pencil, the latter with a tint composed of black, blue, and crimson lake); blisters (prick at back of print), and he advised anyone using silver paper to use a 60 grain bath.

**Haltwhistle.**—The July outing took place on the 20th inst., having been postponed owing to the general election, Whitfield village, a distance of eight miles, being chosen, permission to visit the grounds of Whitfield Hall having also been granted by Mr. Blackett Ord. Twelve members were present, and enjoyed a pleasant outing. The day was fine, and a drive over a most hilly road was full of adventure—a considerable portion having to be done on foot. After arriving at the village and a light refreshment a start was made along the banks of the river Allen, which affords a great variety of excellent scenery, and no difficulty was experienced in spoiling plates. An excellent meal was partaken of at 4.30 at Mr. Hindmarsh's Hotel, and after visiting and exposing plates on the interior of the parish church a start for home was made at 6.30 p.m.

**Herefordshire.**—On 21st inst. the members of the above society held a field day at Hampton Court, by kind permission of Mr. J. H. Arkwright. The weather was all that could be desired, and the party arrived about three o'clock, when Mr. J. S. Arkwright, in the absence of his father, conducted the party over the house, together with the members of the Leominster Society. Tea was provided by the kind hospitality of Mr. Arkwright, after which the President, Alderman Blake, returned thanks to Mr. Arkwright for the very kind reception he had given them. Mr. T. Smith seconded, and it was carried. The party left the Court for Hereford about six p.m., after a very pleasant outing. The results of the competitions are as follow:—May: First, Mr. Jno. Parker, Mr. E. G. Davies; second, Mr. R. Dugdale, Leominster; third, Mr. W. C. Gethen. June: First, Mr. Jno. Parker; second, Mr. E. G. Davies; third, Alfred Watkins.

**Leytonstone.**—The members had a most successful outing on the 23rd inst. to High Barnet, which was reached shortly after 3 o'clock, where the company were met by Mr. Hubert Elliott, of the well-known firm of Elliott and Sons, by whose kindness they were all provided with Barnet plates. Under the guidance of Mr. Elliott the company were piloted round Barnet and Hadley, which is full of historical subjects. The stocks on the green, the high stone, Monken Hadley Church, the old oak commemorating the scene of the Battle of the Roses, Hadley Woods, and various other spots having been

visited, the party were invited to Mr. Elliott's mansion to a most sumptuous repast. The President, Dr. W. Pickett Turner, E.C.C., who had driven over with Mrs. Turner, Hon. Secretary, and others having been introduced to Mr. and Mrs. Joseph J. Elliott, the party were next shown over the magnificent grounds, where boating on the lake and tennis were in full swing, permission having been graciously accorded by the worthy host. Several members had some excellent shots in the grounds. The company were next shown over the house. The pictures (some of which were of great value) were specially admired. Mr. and Mrs. J. J. Elliott having been sincerely thanked for the gracious manner the Club had been received, the party were next invited to inspect the far-famed Barnet Plate Works, at the entrance of which they were met by the Manager, Mr. Birt Acres, who personally conducted, in conjunction with Mr. Herbert Elliott, showing the whole of the premises, several of the managers of departments and others being in readiness to give special information of their respective departments as they in their turn were visited. To describe all that was seen would occupy more space than can be here given to it, as there would be little difficulty in taking several pages, but the carbon enlargements life size of figures and animals, and the Cadett machine for coating plates, for which the machinery in all departments were at work, were especially interesting; in fact, amateurs who see the process that a plate has to go through from the glass crate to the packet of dry plates cannot but marvel how it is we can possess them at the price we do. When the last department had been through, of which there had been about forty, we were surprised, although we had hurried through, it had taken two hours. High Barnet Station was next made for, and Leytonstone reached at 9.45.

**North London.**—On 19th inst., Mr. J. Brewer in the chair, the Secretary exhibited Messrs. Beck's "Frena" hand-camera for films, and Messrs. Houghton's "Shuttle" camera for quarter-plates, which had been lent by the makers for that purpose. The action of the "Frena" in releasing the films after exposure, each film coming to the front in turn, was much admired, as also the various arrangements for sighting and exposing, which have been well worked out in a convenient and practical manner. The peculiar and special action of the "Shuttle" was fully explained, the simplicity and certainty of the changing movement being of especial interest, while the arrangements for focussing and exposing were thoroughly examined and appreciated. The opinion was strongly expressed that both cameras, each for its own special work, should take very high rank among the hand-cameras now before the photographic world. Messrs. Beck's "Bynoe" printing-frame was also introduced and attracted much interest. Satisfactory reports were received of the Eastman chloride paper, most successful prints being shown, and the trials of the Ilford Isochromatic plates had given great satisfaction, one especially fine negative of cherries being shown by Mr. Brewer. Mr. A. E. Smith showed pictures taken with lenses arranged as in an opera glass giving a telescopic result, and the Secretary showed cardboard dark slides made for use with films. No meetings during August.

**North Middlesex.**—On 25th inst., Mr. F. Cherry in the chair, about thirty-five members and friends were present, and three candidates for election were nominated. The Chairman introduced Mr. Bedding, who addressed the meeting on "Photography by Rule." He contrasted the somewhat rule-of-thumb methods of the early workers with the present craze for innumerable formulae, each requiring to be weighed and measured with scrupulous nicety, and each (though compounded to effect the same purpose) differing so widely in their constituent parts that neither science nor judgment seemed to have been consulted in constructing them. He expressed the opinion that the work produced in the early days had yet to be beaten, and that the general average was higher than now. He pleaded for a cultivation of the reasoning powers based upon the worker's experiences, whether successes or failures, and deprecated an implicit trust being put in incomplete tables of exposures and fallible actinometers. He urged upon his audience that all could and ought to acquire technical excellence, upon which those who possessed artistic feeling might base their higher attempts. In the conversation that followed, Messrs. Beadle, Wall, Matthews, Pither, Johnson, Smith, and the chairman took part. Views taken at Kingsbury and Burnham Beeches were then voted upon. The latter competition was well entered for, and the vote of merit was accorded to Mr. Marchant. The remainder of the evening was devoted to technical questions and answers.

**South London.**—Ordinary meeting on 18th inst., Mr. L. H. Graves in the chair. At the conclusion of the ordinary business Mr. J. Miller read a paper "On Photographic Dodges and Combination Printing." After a few hints as to the practical use of the camera, Mr. Miller advocated the use of the following developer, which he had used for a considerable period in Great Britain and South Africa, and with it had been able to develop plates of any make:—(A) Sulphite of soda, 300 gr.; citric acid, 20 gr.; pyro, 100 gr.; distilled water rain water or boiled water, 16 oz.; dissolve

ingredients in order named, each to be dissolved before the next is added. (B) Bromide of potassium, 50 gr.; water, 60 oz. (C) Liq. ammonia, .880, 2 drms.; water, 16 oz. For normal exposures take  $\frac{1}{2}$  oz. each of A and B. In another measure take  $\frac{1}{2}$  oz. of C, adding it to A and B immediately before development. For under-exposure use less of B and more of C. For over-exposure use less of C and more of B. In cases of great contrast reduce the quantity of A. The lecturer stated that he considered every negative, no matter how good, was capable of improvement, and proceeded to explain how this could be effected. Before anything was done he always took a rough proof from the negative. Matt varnish was useful to increase contrasts, as it could easily be scraped away from any part which it was desired to print more deeply. It could also be used to retard or keep back any part that printed too deeply, and afforded a fair surface to retouch or stump upon. Tissue paper without any grain, such as is used by draughtsmen, could be employed to effect similar results, by fastening it on the back of the negative with starch. Portions of this could be cut out with a knife, and afterwards removed easily after damping, or the paper could be made transparent by applying the following mixture with a brush, viz., Canada balsam, dissolved in benzine, using sufficient of the former to prevent the solution spreading when used, and afterwards adding three or four drops of castor oil. Portions of negatives could be blocked out by the application of lamp-black to the paper. Mr. Miller advised the use of a piece of discoloured silver paper in the frame when making prints, to prevent discolouration and contraction. Prints should be washed and toned as quickly as possible. The faces should be sponged before being placed in the toning bath, as this facilitated toning. The bath was made up as follows:—Acetate of soda, 340 grains, bicarbonate of soda, 35 grains, chloride of gold, 4 grains, distilled or boiled water, 80 ounces; keep for a day or so before using. The various methods of producing combination prints on silver paper were dealt with at length. To remove the discolouration from the edges of old plates, and for reduction, the lecturer advocated the following, viz.:—Iodine dissolved in water, using a few crystals of bromide of potassium to bring about dissolution, and adding same to the hypo bath. The solution of iodine must not be too strong.

**Southsea.**—The usual monthly meeting was held on the 20th inst., the President in the chair. The prizes (photographic apparatus) given by the President and Vice-President for the best results of an excursion to Bosham were presented to the winners by the Chairman in an appropriate speech, after which a number of slides were put through the lantern. A series of views of Californian scenery, by Major Wilkinson, R.E., were of special interest. Mr. Hammond exhibited some admirable flower studies, many of which went to prove the marked superiority of isochromatic plates for this branch of photography, whilst his studies of local bits, mostly from hand-camera negatives, left little to be desired. The Hon. Secretary showed a few slides, by reduction, mostly from excursion negatives. A discussion took place on the best method of combining clouds with the subject on lantern slides. Mr. Hammond explained that although many of his best results were obtained by printing on the same plate as the landscape, by masking the latter he also occasionally reduced the sky portion of the negative, and so obtained clouds at one printing. Major Bruno preferred to print them on the cover glass. In connection with the exhibition to be held in October, the Hon. Secretary (Major Bruno, Ordnance Lodge, Portsmouth) will be glad to hear from intending exhibitors of novelties in apparatus new processes, etc.

### SOCIETIES' FIXTURES.

July 29.—RICHMOND.—Show of Prints.

" 30.—BELFAST.—Excursion to Donaghadee.

" 30.—OLDHAM.—Ramble to Plumley for Holford Hall

" 30.—ASHTON-UNDER-LYNE.—Ramble to Crowden.

" 30.—STOCKPORT.—Ramble to Chester.

" 30.—LEYTONSTONE.—Excursion to Greenwich.

Aug. 1.—RICHMOND.—Excursion to Guildford.

" 1.—BRIGHTON AND SUSSEX.—Excursion to Littleworth.

" 1.—CROYDON.—Excursion to Betchworth, Brockham Lime Works, and Reigate Hills.

" 1.—OXFORD.—Walk.

" 1.—S. LONDON.—Excursion to Taplow.

" 1.—CARDIFF.—Ramble to Monmouth and the Wye.

" 3.—S. LONDON.—"Printing Processes."

" 4.—HEREFORD.—Excursion to Malvern.

" 5.—CROYDON.

" 5.—LEWISHAM.—"Hand Camera Work," by Mr. H. L. Davis.

" 5.—RICHMOND.—Informal Meeting.

" 6.—PLYMOUTH.—Excursion to Lopwell.

" 6.—PAISLEY.—Excursion to Kilmarnock.

" 6.—PEOPLE'S PALACE.—Outing, London Bridge to Greenwich.

" 6.—CARDIFF.—Ramble to Newport Canal.

" 6.—WARRINGTON.—Ramble to Halton and Preston Brook.

## To Correspondents.

All communications for these columns are to be addressed to The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by TUESDAY MORNING'S POST.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

## QUERIES.

5772. **Powell's Compressed Gold Baths.**—Can any brother amateur tell me how to get a good black tone by using this gold bath on Ilford's printing-out paper, as when my prints are toned with it they go to a brick-red colour when they are put in the fixing bath? Any hints as to toning will greatly oblige.—PROVINCIAL.

5773. **Hand-Camera Shutter.**—I am about to make a hand-camera. Will someone kindly recommend a suitable shutter for same, not too expensive?—W. E.

5774. **Snap-Shot.**—In developing my hand-camera exposures I am troubled with a want of density along one end of plate or other, chiefly the hinge end of slide. It extends for half to one inch into plate; the image is there with all detail, but the density shades off to edge of plate. I have supposed my camera might be too far in case, and edge of hole casting a shadow over lens be the cause, or is it light leaking in slides?—SNAP SHOT.

5775. **Bromide of Copper Intensifier.**—What is the objection to the use of the bromide of copper followed by ammonia, as an intensifier, as it never seems to be recommended in the photographic manuals? It has the advantage of not being such a virulent poison as the bichloride of mercury as well as being less expensive.—OU BR.

5776. **Bromide Paper Developer.**—What quantity of hydro 10 per cent. solution and carb. soda saturated should be used to make bromide paper developer? Should bromide pot. be used; and if so, how much 10 per cent. solution? How am I to prevent stain on paper when using hydro, and how to clear some already stained?—MICKY.

5777. **Zermatt.**—Will any reader kindly give me information about Zermatt, Switzerland, and the Valley of the Rhone, the best views to take, time of day, and exposure with Edwards' Green Label landscape plates; also inform me if any of the hotels have a dark-room? Exposure would, I assume, be slightly quicker than in England.—H. O. J.

5778. **Dark-Room.**—Can any reader tell me of what place I can use for changing and developing my plates at Penmaenmawr, North Wales, as I am going next month, and there is no dark-room in this place on the AMATEUR PHOTOGRAPHER'S register?—S. L. W.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## QUERIES UNANSWERED.

July 15th.—No. 5756.

22nd.—Nos. 5760, 5761, 5762, 5763, 5764, 5765, 5766, 5767, 5768, 5769.

## ANSWERS.

5762. **Burnishing.**—Make your solution of castile soap 1 oz., to spirit 20 oz.; rub well over the print; when about three-fourths dry, pass through the burnisher, which should be about hot enough to be borne by the hand. Your fault may be in not heating the burnisher enough, insufficient pressure, or allowing the print to get too dry. They should be just dry enough so that the card begins to turn inwards. Always pass the prints through twice, once lengthways, then sideways; if a print will not take the polish, breathe upon it well before burnishing. Many operators use finely-powdered castile soap and apply with a pad of flannel.—EDITOR.

5763. **Whitby.**—Full particulars of Whitby, dark-rooms, places of interest, and a list of plates, to be obtained there will be found in the 1892 "Annual."—EDITOR.

5759. **Weston-super-Mare.**—Full particulars will be found in the 1892 "Annual."—EDITOR.

5770. **Stratford-on-Avon.**—Apart from its associations, Stratford is not a very interesting place, and the following are the principal subjects, arranged in the order they should be taken: Anne Hathaway's cottage, church from Old Lock, theatre, church interior, Shakespeare's birthplace, Guild Chapel and grammar school, church from meadow. A charge of a guinea is made for photographing the interior of the church, but on application to the vicar (Rev. G. Arbuthnot) permission will be given to bona fide amateurs free of charge. The chancel is a difficult subject, as it is usually thronged with visitors. The best time is to go between one and two, when tourists are at lunch, and to use a very quick plate (which must be backed). With a rapid plate and  $f/32$ , an exposure of about eight minutes will be ample in a good light. The view of the church from the meadow will require to be taken in the evening.—J. G. P.

5771. **Fixed Focus.**—I certainly did not understand from Fra's query that by lens  $f/8$  was meant, either by misprint or otherwise, 8 in. focus, or I would have advised him that he could not well pitch upon a more unsuitable lens for hand-camera at fixed focus, than a half-plate lens. This is evident by applying the

formula  $D = 27 \times \frac{1}{f} \times f^2$ , which gives for 8 in. focus lens working at  $f/8$ ,  $21\frac{1}{2}$  yds.; at  $f/11$ , 14½ yds. and at  $f/16$ , 10½ yds., which is too great a distance for average work. The distance can only be reduced materially by employing a small stop, which again is unsuitable for instantaneous work. He had much better get a short-focus single lens, such as is sold at 3s. 6d., and which works well at  $f/16$  with a distance of 4 or 5 yds. With 8 in. focus lens at  $f/8$ , the distance to the ground-glass would be 8 1-12th in.; at  $f/16$ , 8 1-6th in.—W. A. W.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S POST if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

**TOOTLES.**—We hope to forward the prints this week. The combined bath should be filtered before use.

**E. HOARE.**—You do not give us quite enough data to reply upon. But try neutralising your chloride of gold with bicarbonate of soda, about 30 gr. for every grain of gold, then add to the acetate, allow to stand for 24 hours, and after having washed your prints thoroughly free from silver, tone till on looking through them they show no sign of red in the shadows, then fix in a hypo bath made by washing 2 oz. of hypo in 20 oz. of water with  $\frac{1}{2}$  oz. of washing soda added to it. Write again if unsuccessful, and send us some prints to tone for you.

**A. G. P.**—Cover the spot of grease with powdered French chalk, above this place a piece of white blotting paper, and iron with a hot flat iron. You might also try applying benzine with a soft piece of flannel; we prefer the former method, however.

**W. S. BERRIDGE.**—Prints returned this week.

**R. TEGGIO.**—The cut was accidentally omitted, but put right last week.

**E. R. TWIST.**—Obtain from almost any photographic dealer, a few labels printed in English, French, and German, which explain the nature of the contents of boxes. Photographic apparatus and plates are so well known as to cause but little trouble now.

**G. A. CRACE-CALVERT.**—They would come under Inland Scenery; we shall have a special competition next year for them. Many thanks for good opinion of "Annual."

**W. W. NAUNTON.**—Thanks for slides returned, the certificate shall be sent on.

**H. F. LINGING.**—The comparative speeds are 25 and 35 respectively, so that if you give 1 sec. for the ordinary, the rapid will require 3-6ths sec. If you adopt the method of mixing the bath as recommended, it is perfectly safe. You will find a very good paper on toning baths on pp. 12 and 23, July 1 and 8; try the bath recommended there. The paper will give very warm tones with the borax bath.

**F. P. HEATH.**—The effect of your print is very good. We do not think that such prints as yours have been severely handled; it is a truthful representation of what we ourselves saw in Prince's Gardens, when at the Convention, but the only fault we have to find is that the stonework is a little too black; it should be, we think, a shade or two lighter than the nearer tree. Had you used a yellow screen and given a fairly long exposure, you would have got the buildings out clear, but destroyed the effect.

**P. POUTER.**—We publish this week a list of all our competitions, as you ask, still the latest dates are, Inland scenery, October 24th; sea pieces, August 23; and November 21st; portraiture, September 19th and December 19th. The cost of a silver or bromide print would be far above the realms of possibility, and we cannot at present make any changes.

**J. H. D.**—The black speck might be caused through pinholes on the negatives, or by contamination of

the toning or fixing baths with pyro or iron. They are sometimes caused also by iron particles in the paper, but we do not think yours are due to this. When do the spots make their appearance?

**ENDEAVOUR.**—Collotype may certainly be worked by an amateur, and without very much outlay. The simplest process is that of the Autocopyist Company, of London Wall. To explain the collotype process is a little beyond the limits of these columns. Wilkinson's "Photo-Engraving, Collotype, etc.," price 5s., and Schnauss' "Collotype," price 5s., are the best books. Unless you have a lot to do you would find it almost as cheap to get collotype done for you, and we could give you addresses of firms who would undertake your work.

**A. J. T.**—We shall be very pleased to help you further, in any way that we can.

**B. T. NUNNS.**—(1) The paper usually takes about a quarter of an hour to tone. The cause of your particular coloured prints is due to the use of a simple sulphocyanide and gold bath; see our issue of July 8th, p. 22, second column, for reason, and also for improved formula. (3) Yes, the acid is right. (4) The addition of ferrocyane is beneficial and worth using.

**J. BENNETT.**—Wilkinson's "Photo-Engraving and Collotype," price 5s., and Schnauss' "Collotype, Photo-lithography," price 5s.; both can be had from our publishers.

**T. J. STANLEY.**—The bath will work all right if filtered. You will find a very good formula on p. 22, July 8th.

**H. B. HARE.**—Letter received with thanks, entry form shall be sent on.

**H. T. BABINGTON.**—Either your fixing bath is acid, or else you have been fixing pyro-developed negatives or iron-developed bromide prints in it. Make a fresh bath, be very careful of clean dishes, etc.; Add  $\frac{1}{4}$  oz. of washing soda to the solution, and then try again.

**FIX.**—(1) Printed too deep, or else negative insufficiently developed. (2) Negative under-exposed, printed too deep. (3) Negative too thin, over-printed, over-toned. (4) Under-printed and over-toned. (5, 6, 7, 8, 9) These strike us as being from fogged negatives, are all over-printed and over-toned. (10) Under-printed and over-toned. Your work shows very great want of knowledge, probably in developing—you are using too much ammonia, and thus fogging your plates, and consequently not getting enough density.

**THOMAS CLARKE.**—The Supplement appears this week.

**A. J. GARWOOD.**—You can either use Howard Farmer's ferridcyanide reducer, or else Belitzski's; the former is easier prepared. When using Eau de Javelle you should make a solution of chrome alum 20 gr., water 1 oz., and mix equal quantities of this with Eau de Javelle and water, and then apply. To remove the mercurial intensification, paint with hyposulphite of soda solution.

**PLATES.**—The marks on your plates are due to their being light-fogged, or else imperfect fixation, or using an alum bath before or after fixing without washing; the first is, we think, the cause, however. Do you want plates back? If so, send address.

**A. F.**—(1) The advantages of having a camera brass bound, is that it is much stronger and less liable to warp or swell from the effects of heat or damp. (2) In using the eikonogen developer you mention, to accelerate it add more of solution to the washing soda; to restrain it, add more water or lessen solution B, or preferably add bromide of potassium to it.

**W. M. HANKINSON.**—Piper and Carter, 5, Furnival Street, E.C., publish the book you name at 2s. 6d., or our publishers would send it to you.

**W. H. BIBBY.**—Print duly received and entered, we fancy it will come out pretty high, but wait and see.

**BROMIDE.**—Place the lantern in a wooden sugar box, and allow holes for ventilation. You would find instructions for this in our last volume, where a series of articles on enlarging were included. You can easily enlarge from quarter-plate to whole-plate.

**A. BRAINE.**—Many thanks for print, which we may use.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence. Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the AMATEUR PHOTOGRAPHER, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of a buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques or Postal Orders, made payable to **Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.**

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number, the name and address being registered, and letters forwarded for a fee of 8d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the Editor, **AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C.**, who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

**Background.**—For sale, background, interior, new, very cheap.—James, 10, Mount Street, Camberwell Gate.

**Bicycles, Tricycles, etc.**—Diamond-frame, cushion-tyre Safety for disposal, ball bearings, perfect condition, only new short time back, nickel-plated, accept £6 7s. 6d. for immediate cash, rare bargain; approval; satisfaction certain.—T. W., 6, Tower Street, Ipswich.

**Cameras, etc.**—Lancaster's quarter-plate Le Merveilleux, with chemicals, complete, bargain, 2s.—Mapleston, 95, Lordship Road, Stoke Newington, London, N.

12 by 10 camera by Perken, Son, and Rayment, long extension, double swing back, all movements, three double dark slides with carriers down to quarter-plate, cost £17, will take £8 10s.—A. W. Dron, Dyne Road, Brondesbury, N.W.

Lancaster's half-plate Instantograph camera, perfect, 25s.; exchange.—George, 55, Percival Street, Clerkenwell.

## OUR VIEWS.

"To hold as 'twere the mirror up to nature."—*Shakespeare*.

The Monday Afternoon "At Home" is discontinued for the present, but will be resumed on Monday the 5th of September.

**OUR VIEWS.**—Announcement—Holidays with the Camera Competition—Our 1892 Annual Lantern Slide Competition—Dark-room at Llandudno—Loaning of Prints and Slides—The Convention Hand Camera Division.

**LETTERS TO THE EDITOR.**—A Correction (Perkins)—The Blister Fiend (H. S. Large)—One Good Use for Spoilt Plates (S. E. Venn).

**LEADER.**—Bromide Paper.

**ARTICLES.**—General and Photographic Chemistry (Conrad)—The Photographic Convention: Deficiencies in the Training of Photographers (Howard Farmer)—How to Make a Set of Photographic Apparatus (H. J.)—Photography by Rule (Bedding)—Notes on Professor Armstrong's Paper, "The Theory of Development (Elder)—Film Enlarging by Cresco-Fylma.

**SOCIETIES' MEETINGS.**—Aberdeenshire—Cleckheaton—East London—Hackney—Liverpool Camera Club—Liverpool.

**EDITORIAL DEPARTMENT**—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

### TERMS OF SUBSCRIPTION—

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	6s. 6d.....	13s. 0d.
OUT OF POSTAL UNION ..	7s. 9d.....	15s. 8d.

**TRADE ADVERTISEMENTS** are received up to Tuesday morning.

**PUBLISHING DEPARTMENT.**—All letters containing Subscriptions, Orders, Remittances, SALE AND EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZELL, WATSON, and VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE AND EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

OUR annual "Holidays with the Camera" competition closes, as announced last week, on the last day of this year, and the following are the rules and conditions:—

**PRIZES:**—Gold, Silver, and Bronze Medals, and Certificates, with special prizes of "Niepce" or progressive medals for past prize-winners.

**SUBJECTS.**—All photographs are eligible that have been taken during the "holidays," but must be landscape or sea pieces with or without figures, views of towns, photographs of cathedrals, churches, public buildings, etc., but not portraiture, figure study, or pictures which could be classed as "Photography at Home." The prize pictures will become the property of the proprietors of the "AMATEUR PHOTOGRAPHER;" other photographs will be returned if stamps be enclosed to cover postage.

**NUMBER.**—Not more than twelve or less than six prints are to be sent in. They must all be mounted and numbered to correspond with the numbers in the MS. They will be judged upon their merits as a whole.

**DESCRIPTIVE NOTES.**—Each competitor must contribute a short account of his holiday, to be not less than 500 or more than 1,000 words.

**DATE.**—All photographs must be received on or before the 31st December, 1892.

As this may practically be considered the commencement of the holiday season, we trust many of our readers will not forget our competition during the holidays, and try and send us some excellent work. Prizes cannot, unfortunately, be awarded to all, but open competitions are extremely good educating means for workers, by seeing how they stand with regard to fellow-workers.

As we have already announced, the AMATEUR PHOTOGRAPHER 1892 Annual Lantern Slide Competition closes on September 30th, and we shall be glad to receive applications for the same from the Secretaries of societies as early as possible. Unfortunately, last year considerable disap-

"Amateur Photographer" Monthly Competition, No. 39.—  
"SEA PIECES OR RIVER SCENERY." Latest day, August 22nd.—  
Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, September 16th.)

pointment was caused by certain societies not receiving the slides in time for the appointed exhibition. We hope to obviate that mishap this year, by limiting the number of exhibits in each week to three—so that if shown on a Monday they will not be shown again till Wednesday and then Friday.

We also intend having a special case made for them of much lighter construction than last year, and thus hope to be able to save some of the carriage, which in some cases was very heavy.

Form of application for the slides will be forwarded to the Secretary of any photographic society on receipt of stamped addressed wrapper; in all cases Secretaries are requested to give three optional dates. The following are the rules on which the slides are loaned:—

1. A booking fee of one shilling must accompany every application.
2. Carriage both ways to be paid by the applicant (except as provided in No. 4).
3. All loaned lantern slides to be returned, or forwarded, as advised, the day after exhibition.
4. The loaned lantern slides must be returned to the head office, 1, Creed Lane, Ludgate Hill, E.C., or forwarded to such address as may be advised, in the latter case the consignee will pay the carriage.

We publish on this page a note from a correspondent as to the completion of a dark-room at Llandudno, which will, we are sure, be useful to those who may be visiting there this summer. We shall always be glad if any of our readers will kindly inform us of any dark-rooms they may discover or hear of. Our "Holiday Guide" in the "Annual" contains a great many dark-rooms, but as we desire to make it still more complete and comprehensive for next year, we shall be glad of any notes or information of places not mentioned there.

Photography is becoming every day more recognised as one of the hobbies and amusements which should be popularly supported by prizes and medals. It is unusual to see a flower show, or, in fact, any exhibition that has not a class or classes devoted to photography. The annual flower show of the Hendon Parish, Sunderland, which will be held at the end of this month, has two classes, but both are confined to local workers. We shall always be pleased at any time to assist such exhibitions by loaning lantern slides, or prints for the decoration of the rooms, etc.

Mr. Welford is desirous of arranging a friendly informal meeting in London, of the hand camera division at the Convention, to show results, compare notes, and quiet chat. Anyone interested in the hand camera work is cordially invited. Those workers who can attend on or about Wednesday the 10th inst., and who can bring prints from their negatives, are invited to drop a post card to 47 Hagley Road, Birmingham. The gentlemen (or ladies) who secured shots but are unable to attend are invited to forward the prints to Mr. Welford, who will take charge and show them. Exact date, time, and place will be sent to each one direct by post.

**Amateur Photographic Association.**—The annual meeting of the council of this society was held on the 27th ult., at 58, Pall Mall, his Highness the Duke of Teck in the chair. The pictures contributed by the members for the current year, which had been arranged and classified by Mr. Glaisher, vice-president, were examined; and prizes, consisting of silver goblets, pictures, albums and medals, were awarded to Viscount Maitland, Vicomte de Condeixa, Mr. R. O. Milne, Mr. Hobson, Mr. Stephens, Mr. Murray, Mr. Leventhorpe, Mr. de Dechy, Mr. Cohen, Mr. Dresser, Mr. Harrison, and others. Mr. Melhuish, the hon. secretary, stated that never before had so large a number of pictures ranking in the "first class" been contributed.

## Letters to the Editor.

### A CORRECTION.

SIR,—Will you kindly allow me space to point out as an inaccurate statement in my article on "Architectural Photography" in your recently issued "Annual," which I became conscious of having made only after correcting the proof sheets. On page 112 I speak of the sun being, roughly speaking, due east at six a.m. I should have said midway between north and south, measured along its own daily path, and since this is not even approximately parallel to the horizon, save in the neighbourhood of the poles, this point is not above or below the eastern point of the horizon; in fact, only twice during the year will the sun be in the east at six a.m.; from the vernal to the autumnal equinox it will be to the north of east, and during the other half of the year to the south of east; the exact amount of this variation depends on the latitude and the time of year. The result of the obliquity of the equator to the horizon will be that in England the sun will rise rather more to the north of east in the summer than I stated.—Yours, etc., T. PERKINS.

\* \* \* \*

### THE BLISTER FIEND.

SIR,—Without my being deemed presumptuous may I be allowed to say a few more words? It is entirely our own fault if we now get blisters on albumenised paper, for the fiend can be perfectly "spirited" away. It is a most complete preventive, and if used as set forth in your issue for 8th July, the same spirit will answer over and over again, used in a cleanly way. In saving prints it pays for itself many times over, and no other preventive need be used. I am very sorry to pick a bone with "The Baron," but I must say, for the good of photography, that his advice is anything but thorough, and it would not be fair business to palm off prints afflicted with (to him) hidden blisters. Let him try some printing for the trade, and he will soon find they have got splendid eyes; and I wonder if he has ever properly burnished such prints, and yes or no, the blisters are there, and in not a very long time will show where, by the colour fading before it does on the other parts of the print, firstly because the surface is unequally supported, secondly because those parts where are the blisters cannot be so thoroughly freed from the chemicals as the surrounding parts. The blisters with which I was troubled are those known by some as "blebs," varying from the size of a threepenny piece to that of a large filbert. But by using methylated spirit, blisters are quite done with; therefore why neglect a remedy so simple, certain, and saving?

If you think fit to print the directions once more, here they are. First wash out the free nitrate as usual in water, then tone, then wash for say seven minutes in gently running water, now immerse one by one in pure spirit for five or ten minutes (according to the number of times it has been previously used), then with one hand take them one by one out of the spirit, using your other hand for putting in the fixing; you will thus keep the spirit from getting contaminated with hypo; let them remain the usual time, then wash two or three hours in running water, and the manipulation is perfect.—Yours, etc., H. S. LARGE.

**Llandudno.**—Photographic dark-rooms for the use of visitors to this favourite watering-place are now completed, fitted up regardless of cost, with every latest improvement, well ventilated and lofty. Accommodation is provided for three to develop at one time, and the fittings include large fountain, rose taps, brilliant Argand gas lamps, roomy sinks, developing trays from quarter-plate to 15 by 12, glass measures, hypo dishes with fresh solution ready for use, negative washing tanks with a constant stream of water, drying shelves, roomy lock-up cupboards for holding cameras, plates, negatives, or any other article an amateur may wish to lock up, and the key of which is in his possession (every cupboard has a different lock and key); each room has a large window so that the heat of gas is avoided in the daytime. Two Aptus, white, self-lighting gas burners are fitted, so that lantern-slides or bromide prints may be made at any time. Plates of all sizes, and fresh from the makers, pyrogallie, ammonia and hydrokinone developer (two solutions each) can be obtained at the rooms, which are open from 9 a.m. to 10 a.m., and an attendant is constantly on the spot. The rooms are situated in the most central position in Llandudno, viz., in the gallery of the market hall, Gloddaeth Street, exactly opposite the general post office. Arrangements have been made by which the Llandudno Camera Club will make these rooms their head-quarters, and the Hon. Sec. will be most happy to give intending visitors any information respecting this most beautiful locality on their writing to him, care of the rooms as above.

## BROMIDE PAPER.

## II.—DEVELOPMENT.

TO DEVELOP, it is essential that we should have a developer, and, as already pointed out when treating of the development of enlargements, it may be either ferrous oxalate, hydroquinone, or eikonogen. Of the three, the last is our favourite, but as others use ferrous oxalate we will consider it first.

*The Ferrous Oxalate Developer.*—Actual formulæ for this have already been given (page 464). We now come to the modification of the developer to suit the negative; we will again take our three typical negatives, thin, normal, and hard. For the thin negative wanting in contrast, we mix our developer in the proportion of 1 of iron to 5 of potash, and add 5 drops of a 10 per cent. solution of bromide of potassium, and flooding the print with this allow it to act till development is complete.

The normal negative requires slightly different treatment; in this case it is far preferable to reduce the quantity of iron and bromide, using on the whole one part of iron to six of oxalate, and adding merely one drop of bromide solution.

For the extra hard, full-of-contrast negative we work quite differently. We mix one part of iron to four parts of oxalate, and add one drop of bromide, and flood the print with this and rock the dish, and allow the picture to come up, which it will do without harsh contrasts. Or another method of working this class of print is to add one part of iron to twelve parts of oxalate, and a drop or two of bromide, and patiently rock the dish to allow the whole of the image to come up, and when all detail is out, add five drops or even more, and two more parts of iron, and allow the image to gain density.

Dr. Vos has another method of treating prints, which we give in his own words:—

"MODIFICATION OF IRON DEVELOPMENT.—It is generally said that iron development cannot be controlled, but I maintain that it can be, and remarkably so, *if the iron be added little by little*. Suppose, for instance, that I have printed from a thin negative, which will be likely to be too much exposed, I proceed thus: Say I am developing a quarter-plate print; one ounce of developer is sufficient. I first measure out two drachms of the iron into a small phial of that capacity, the maximum dose that I can employ with one ounce of oxalate. I then put into the developing glass the ounce of oxalate, then the two drops of bromide, and lastly (important) only a sixth or a fourth of the iron, shaking them up thoroughly together. After a short preliminary soaking of the paper in plain water to ensure the developer acting regularly, I pour on the mixed developer. Details will come up quite slowly, and if the picture hangs fire, and will not develop up to brilliancy, I add a few more drops only of iron. This will start it afresh, but most likely the extra drops will not be required. To ascertain if the print be developed up to proper density, hold it to the developing lantern and view it by transmitted light. I can now wait until all details are out, and no staining will take place of the paper, even if the development be prolonged, provided that your developer be just acid, and provided, too, that you take care to wash thoroughly with acidified water (acetic acid is best for this) before fixing. Omit this and your prints will be stained yellow when finished. For washing I employ three changes of acidified water, and give a good final rinse with plain water. The time the prints wash in this is more important than the number of changes you give. I allow about half a minute washing with each change. After the first washing with acid water you can work with yellow light without any fear of fog, and I would also mention that bromide paper—my Eastman's, at any rate—can be developed close up to a lantern guarded only by a single sheet of ruby glass. Mine has a bright gas flame in it! I never have fog. While the details are coming up, say in a view, the foreground may get a bloom-like deposit of lime (?) on it, whilst the distance (which is generally the denser in a negative) is coming up. This bloom will fix off instantly in the hypo. After prolonged iron development, when the print is fixed and dried, deposit marks will probably be seen on the surface of the print by reflected light. These marks will not be noticeable unless the print be held and viewed aslant. They may, however, be removed by weak hydrochloric acid and a piece of cotton wool rubbed lightly. I would mention that this tentative method of

iron development can also be used for plates. The marks on the dried negative can also be removed by hydrochloric acid. Both with prints and negatives it is better, perhaps, to employ this weak acid with cotton wool, when thoroughly washed after fixing, to ensure them having a bright surface. It is important that the hydrochloric acid water be very weak—just acid to the taste or a little stronger—otherwise the depth of the negative or print will be destroyed and the fine detail eaten away. It will be found that the second and third and fourth print or negative developed with the same one developer will each succeeding one be more marked thus when finished than the first one, which will be scarcely marked, especially if development has been rapid. This is due to the iron becoming more and more oxidised by contact with the air. The developer, too, will probably be found to be getting somewhat thick. Now, after developing the first print, if I have next to develop a print from a thin negative, I would add only a few more drops of the iron. In this way I have used only half the whole allowable quantity of iron for several prints, allowing the iron to exercise its full effect, and getting well deposited to blackness in each print. If the exposure be correct, the print will not develop to more than a certain blackness, especially so if under-exposed. The exposure estimated by my opal glass method is a little more than the exact exposure. If you add the whole of the iron all at once, with a print from a thin negative, the whole picture is likely to cloud over. Now, for developing a print from a negative with some density, you can commence with as much as half of the iron at once; indeed, the picture will require it, if the negative be dense, to fetch up details at all. By this method of adding the iron by degrees it is the *oxalate* that at last gets used up, not the iron, until at last—up to six prints, about—the developer is effete, and fresh must be made up. Of course, as each succeeding print (or plate) is developed with the same developer, the action gets weaker, because the constituents are more diluted, part of them having been worked out from the solution. If you develop a print from a *dense* negative first, and have added, say, half the dose of iron, and you next develop a print from a *thin* negative, be careful not to add more iron until you have seen the effect on the picture. You can also slow iron development by diluting your oxalate solution, also by diluting your iron; but in these cases exposure must have been longer, and you must give plenty of time for density to come up; the result is as good in the end, though the dried print will be more marked than ever. If you have only one print to develop it is useful to thus dilute your solutions, so as to save using so much of the oxalate and the iron. Diluted solutions, too, will save a print or plate that is *known to be over-exposed*. Slowing in this case can also be done by the slow addition of iron, which is the best method—I think a better than adding more bromide, for if bromide be added it exerts such a checking action as to absolutely keep back the details in the higher lights, however much you may develop; but with the tentative method the details will at last come up, unless the exposure has been too short. The solutions in the case of diluting will be somewhat thick, but this will not matter with prints provided there be no positive precipitation of the iron. For negatives, however, never use diluted developer; they will veil over. Again, you can get a perfect print even with a solution of oxalate that has too much iron in it and that *has* deposited a precipitate. But before fixing rub it well over with acidified water and a piece of cotton wool, giving it also a prolonged washing in the acid water, and the whites in the paper will remain pure in the finished picture, but it is risky. The dilution with water seems to oxidise the iron by the oxygen that the water contains, and so renders the mixture muddy. If with diluted developer the development be not well pushed, the print after fixing will be of a brown colour and unpleasant to look at. I would mention in passing a means of avoiding air bubbles on bromide prints or glass negatives. The usual advice is to employ a camel-hair brush, but if you give the paper or the plate a preliminary minute of soaking in water before developing, and agitate them when immersed violently for a few seconds from side to side against the sides of the developing tray, no bubble will remain. I never have a bubble by any chance by this means. Now, as to fixing. I use generally only 4 oz of hypo to the pint; prints (or plates) left in this even for an hour will not harm, though in a stronger fixer they would be materially injured. In fact, you need not employ more hypo than just the quantity required to fix out the unaltered bromide of silver in the print (or plate), or a slight excess for safety. What is the exact proportion of hypo required to fix a certain amount of silver I do not know. If a small quantity of hypo be used for fixing, of course the process will take a longer while, and you should leave the prints (or plates) in the fixer for many minutes, and after in the case of negatives all the white bromide of silver has disappeared. You can save your hypo, though, considerably by this means, suppose you wish to fix only one or two prints or negatives. Another point in iron development is to work with clean dishes, glasses, bottles, etc. I always keep some strong sulphuric acid by me, and also a mop fixed on a piece

of wood, and if the developing glass, or tray, or bottle have any deposit of iron on them I pour in a little of the acid, fill up with water, and mop out, and finally rinse. This little extra is not much trouble, but is most important for clean work with iron development."

#### HYDROQUINONE DEVELOPMENT.

We do not like hydroquinone as a developer for bromide paper. It either has a tendency to block the shadows greater than iron, or else gives rusty prints, and when a caustic alkali is used frequently causes a metallic and iridescent fog, which degrades the whites.

To modify this developer is as easy as with iron. Increase of bromide means increase of contrast; lessening the bromide and increase of the alkali means lessening the contrast, and the same effect may be obtained by diluting the developer, and no further notes are required after the development of enlargements has been read.

#### EIKONOGEN DEVELOPMENT.

The developer we use is Dr. Stolz's, given on p. 484, and this is modified in the following manner. For thin, weak negatives the quantities should be 7 parts of A, 2 parts of B, and 15 parts of water; for normal negatives, 5 parts of A, 2 parts of B, and 18 parts of water; for harsh contrasts, 5 parts of A, 4 parts of B, and 22 parts of water. Bromide should not be used, or rusty tones will be given.

It was our intention to treat of the clearing and fixing of prints, and to conclude with some general observations, but we think we have sufficiently considered the remaining elements of success in talking about enlargements, to which articles the reader must refer.

## General and Photographic Chemistry.

By E. C. CONRAD, F.C.S.

#### INTRODUCTION.

PHOTOGRAPHY is the art of obtaining the representation of objects by the agency of light upon sensitive substances. Photography requires at every stage, and in all its branches, the use of certain chemical compounds, and it is to a consideration of these, their preparation or method of manufacture, properties, &c., and especially their uses in photography, that we propose more particularly to devote ourselves, but to make their relationship plainer and these articles more generally useful, we have included several substances that are not at present directly employed in the art.

Before commencing a consideration of these substances it will be well to state and explain both the general laws and terms used in connection with chemical science.

#### GENERAL LAWS AND TERMS.

*Chemical Compounds and Mechanical Mixtures.*—Powdered iron and sulphur can be mixed together very intimately, but no matter how small the individual particles may become, they still remain iron and sulphur, and can be seen as separate grains by a microscope, or the iron separated by a magnet. They are merely mixed, and can be separated by mechanical means; each particle has its separate and peculiar properties. If the mixture is heated, the physical properties are entirely changed, the individuality of the iron and sulphur is lost, and their presence can no longer be detected, nor can they be separated by purely mechanical means. They form a chemical compound.

*Laws of Chemical Action.*—Chemistry being an exact science is governed by fixed laws, of which the most important are: (1) Chemical combination is always accompanied

by an alteration in the physical properties of the constituents; and by a change of temperature some combinations produce cold and some heat, often to a marked extent. (2) Any chemical action taking place under any conditions, can always be relied upon to take place to exactly the same extent under the same conditions. (3) A variation of the conditions produces a variation of the result.

*Elements.*—Chemistry embraces a consideration of the composition of every substance in existence, and it has been found that it is possible to reduce all these to some sixty-three elementary bodies; that is, substances that cannot be, as far as we know at present, split up into any simpler form.

*Symbols.*—To facilitate reference, and to enable the action of these elements to be explained concisely, chemists have introduced a system of shorthand in which every element is represented by a symbol or sign; such symbols are often the first letter of the English or Latin name of the element itself. When it happens that the names of other elements commence with the same letter, another is used in conjunction, the first letter in all symbols being a capital, the other a small one.

*Atoms.*—The smallest obtainable division of an element by chemical means is called in chemical philosophy an atom, and is supposed to be incapable of existence by itself.

*Molecule.*—A group of atoms, or the smallest obtainable division of an elementary body by mechanical means, is called a molecule, and is capable of independent existence.

*Atomic or Combining Weight.*—The atoms of all the elements have a fixed weight or value expressed in proportions of hydrogen (the lightest body known). This weight is called the atomic weight of the element, and is understood to be represented whenever the symbol of an element is written.

All the elements unite together in the proportion or multiple of their respective atomic weights. Example: The gas oxygen has the atomic weight of 16, and whenever it enters or leaves a chemical compound it is always in this ratio—as 16 or 32 or 48 or 64, &c.

The atomic weight of a compound is the total weight of its elements.

*Chemical Formulae.*—When a compound or union of one or more elements has to be represented, the symbols of its elements are written one after the other, forming what is called a chemical formula. Example: The compound called silver chloride or argenti chloridum is represented by AgCl, and this formula means that one combining weight of the metal silver (=108) is united with one combining weight of the gas chlorine (=35.5).

*Chemical Nomenclature and Equations.*—To explain the action of the elements or their compounds on one another, some mathematical signs are used, viz., + plus or added to; = equals or balancing; — minus or subtracting; and these signs, with the symbols of the elements or compounds, make up what is called an equation. Example: Two parts or atomic weights of the gas hydrogen (=1) unite with one part or atomic weight of the gas oxygen (=16), to form the liquid water, and this action is expressed by the following equation,  $H_2 + O = H_2O$  ( $2 + 16 = 18$ ). It will be noticed that the sum of the atomic weights on each side of the balancing sign are equal, and this is always so in all correctly written equations. Small figures written after a symbol and below the line show how many atomic weights of that element are included. Large figures written in the same line as the symbols multiply all the symbols following after it up to a sign or full stop. Example: Calcium nitrate has the formula  $Ca_2NO_3$ , in which the 2 multiplies both the nitrogen and oxygen, whereas the 3 only multiplies the oxygen, the whole formula showing that one combining weight of

calcium is combined with two of nitrogen and six of oxygen.

**Brackets.**—The nitrogen and oxygen in the above example could be written in brackets ( $\text{NO}_3$ ), in which case the figure multiplying them could be placed before or behind the bracket; above, on, or below the line.

**Radicals.**—Groups of elements which enter or leave combination together are termed radicals, but as this term could be applied to the elements themselves, it is usual to speak of groups as compound radicals, and if they originally existed in combination with hydrogen as acids, they are spoken of as acid radicals.

**Atomicity, Valency, Equivalence.**—The elements can be arranged and named according to the number of atoms of hydrogen they are equal to or can replace under favourable conditions. These values can be shown by placing dashes or Roman numerals over the symbols to show their respective values.

The following are the terms employed, with examples of each class:—

Monads, or monatomic, equal to one equivalent or combining weight of hydrogen	$\text{H}^1, \text{Cl}^1, \text{Ag}^1.$		
Dyads, or diatomic, equal to two equivalent or combining weights of hydrogen, $\text{O}^{II}$ .			
Triads, equal to three equivalent or combining weights of hydrogen, $\text{Au}^{III}$ .			
Tetrads, " four	"	"	$\text{Cl}^{IV}$ or $\text{III}.$
Pentads, " five	"	"	$\text{N}^V.$
Hexads, " six	"	"	$\text{S}^{VI}.$

**Graphic Formulae and Bonds of Force.**—To show the composition of complex compounds, it is sometimes advantageous to write the elements composing them with their valency expressed by imaginary lines, called bonds of force, and such a representation is called a graphic formula.

Thus the action of potassium on sulphuric acid and the resulting compounds can be expressed as follows:—

Sulphuric Acid,	Hydropotassic Sulphate,	Potassium Sulphate,
$\text{H}_2\text{SO}_4.$	$\text{HKSO}_4.$	$\text{K}_2\text{SO}_4.$
O	O	O
S < O—H	S < O—K	S < O—K
O	O	O

The sulphur being a hexad is represented with 6 bonds.

The oxygen " dyad " " 2 "

The potassium and hydrogen being monads are represented with 1 bond each.

It must be distinctly understood that these so-called bonds of force have no actual existence, and are only used to express an energy or quality of which we know nothing, except its results. Many of the elements form compounds of different atomicity; for instance, phosphorus and arsenic sometimes combine as triads and sometimes as pentads; and lead sometimes as a dyad or tetrad. This difference of behaviour is to be accounted for on the assumption that a pair of these bonds of force are latent or perhaps combined together in the compound of lower atomicity. As they always appear or disappear in pairs, it follows that an element that forms fully saturated compounds of high atomicity may also form compounds of less atomicity differing from one another by two or more equal numbers of powers. Thus a hexad may act as a tetrad, or even a dyad, but not as a pentad, triad, or monad.

**Chemical Affinity.**—The quality or force which brings about the combination of the elements and governs its extent is called chemical affinity.

**Analysis—Qualitative and Quantitative.**—In order to determine the composition of a compound, it is often necessary to decompose or reduce it into its elements or some simpler compound; such a process is called an analysis. If it is undertaken to determine the substances present, it is

called a qualitative analysis. If to determine their proportion or quantity, it is spoken of as being a quantitative analysis. It is usual to express the results of an analysis in percentage of composition.

**Synthesis.**—Instead of separating a compound, it is often possible to cause it to combine with some other element or compound; such an operation is called a synthetical process.

(To be continued.)

## The Photographic Convention.

DEFICIENCIES IN THE TRAINING OF PHOTOGRAPHERS.

BY HOWARD FARMER.

EARLY GUIDANCE.

WHEN it is known in the early life of a lad that he will probably become a photographer, his training should commence during the latter years of his school life. His studies can then be guided in directions which in after years will be directly useful to him in his professional capacity, and he will acquire knowledge rapidly that may later save him much labour and effort.

Where this has been done it will generally be found that the directing parent has been a photographer or connected with photography, and in such cases the same forethought which has guided these early studies into useful channels has probably continued this direction to a successful *dénouement*.

IMPORTANCE OF CONTINUITY.

But the majority of those who become photographers have their career decided after leaving school—sometimes a good many years afterwards—and it is to these my remarks more especially apply. As an example we may suppose a lad has left school, and not until he has subsequently spent a year or more in holiday-making is the important decision made as to what his life's work shall be, and steps are taken to start him on his career.

Now, while the whole of our sympathies may go to aid the lad's pleasures in the heyday of his youth, the stern competition of life enforces the doctrine that this, the most valuable portion of his life from an educational standpoint, must be utilised to the utmost, and in doing this there is no need to deprive him of his pleasures, but they must come in as a complement forming natural divisions to his work.

It is well known among teachers that the assimilative power for new knowledge usually falls off very much after the age of twenty or so is reached. This is especially the case when a lengthy gap or interval has been allowed to occur in the training; and a mass of evidence to support this occurs with photographers in the very small proportion who, however hardly they may be pressed, attempt even to increase their knowledge; and the steadfast application required from those who do. It is not too much to say that, independent of the inferior value which knowledge acquired at the age of twenty-five to thirty possesses, as compared with the same knowledge acquired at from fifteen to twenty, the labour and application necessary in its acquirement is three or four times as great at the more advanced age.

It is from considerations such as these we are forced to conclude that in allowing a lad's training to stop suddenly when he leaves school, if only temporarily, for a year, not only are the best fruits, which might readily follow from the cumulative effect of his previous training left ungathered but before he has arrived at an age when he himself may fairly be held in some measure responsible, his future status is placed in jeopardy.

INSUFFICIENCY AND UNCERTAINTY OF THE APPRENTICESHIP SYSTEM.

We may next suppose that the lad forming our example is apprenticed or placed to learn his trade with some firm of photographers. In accomplishing this, the parent may frequently consider that he has now fairly started the lad on his career, and, so far as any further training is concerned, leaves it to the care of his employers and the lad's own devices.

Almost universal as such a method of starting a photographic career is, the demonstrable insufficiency of such a procedure is only too complete. In the first place, the professional education, excepting so far as acquiring manipulative skill and a knowledge of some aspects of the commercial economy of the business is concerned, leaves off where it ought to begin, and, although no one will hesitate to admit the prime importance of manipulative skill and of business methods, the trained photographer nowadays requires a great deal more in order that he may attain any *status*. In the second place, even the manipulative work is confined to one or two specialities, whereas the student wants at this, the very early stages of his career,

and before specialising, trial practice in all branches. Thirdly, the skill acquired will depend largely upon the attention devoted to the student by the employer and fellow *employés*, which introduces an element of uncertainty into the training, and to which may be added the inevitable proportion of time which is wasted or during which no progress is made. There are also other reasons, which at first sight are not so obvious, why the old system of apprenticeship, which is fast disappearing in other trades, must also in photography disappear, or be largely modified and supplemented, in order that the photographer may not only acquire an honourable *status* in his profession, but also keep a distinct level above his neighbour the amateur.

#### TECHNICAL AND ART TRAINING—THE PRIME NECESSITY FOR.

After his training has commenced, our supposed young apprentice finds there are at least five distinct sides to his subject, as follows:—

1. The Practical or Manipulative.
2. The Technical.
3. The Commercial.
4. The Artistic.
5. The Scientific.

Each of which requires his attention in a greater or less degree depending upon the character of the work to which he intends devoting his abilities. To convey some definite idea of the average relative importance of each of these divisions, it will be necessary to consider them individually.

1. *Practical*.—The manipulative skill required for most branches of photographic work is not of a very high order; for example, the actual operations involved in the taking of a portrait or landscape negative are all of a fairly easy character, and require but little experience and practice on the part of a student to perform them with regularity and success. Notwithstanding this, the chief help which the student usually derives from his work with his employers is confined to a sufficiency of experience in these easily acquired manipulations. There is, however, one special branch of studio practice which requires a very high degree of skill, and that is retouching, and in other departments of photography, such as working large wet plates successfully, some portions of process work, and others, considerable manipulative skill is essential.

2. *Technique*.—It is not difficult to show that the main foundation of photography, as a profession, lies in its techniques.

Whether in the artistic or scientific departments, in landscape, seascape, motion, architecture, reproductions, or printing processes, the worker who is trained in either of them is the one who excels; and on examination, it is found that the success depends not so much upon any particular difficulty in performing the necessary operations as upon a *complete familiarity with the minutiae and details of procedure*, which give the best result under particular conditions. The reason that several years' training is commonly necessary to get a full percentage of successful results in any one of them is due to the fact that the worker has not had the opportunity of learning in a systematic form the *minutiae* and special factor which govern different classes of work, but is left like a man groping in the dark to find his way slowly and laboriously by the method of trial, and, even if he has the guidance of a fellow-worker, it is one who has found it himself by trial and experience, and can only impart it in the same manner.

Take two beginners of identical abilities, perseverance, and general education; give both the average training obtained as apprentices to a photographer, and give one of them, in addition, systematic instruction in *technique*. The latter will become as good a photographer in one year as the former will in four years, and will ultimately become a much more competent and independent worker.

3. *Commercial*.—Important as a training in commercial economy undoubtedly is, and which includes such subjects as economy of time, material and wages, value of specialism and enterprise, punctuality, tact, and politeness, treatment of employer and *employés*, accommodation to circumstances; in fact, all the *minutiae* which together form the system of a successful business man, this side of his training is one which, in great measure, would be the same in all trades, and which therefore is rather included in his general education than in his specially photographic one. That photographers as a body are behindhand in this department of their training is, however, a fact very widely conceded.

4. *Artistic*.—The value of an art training is second to none in the whole range of a photographer's studies, as it invariably gives the stamp of superiority to his work. This is abundantly testified in public displays of photographs, where the pleasing effects in light and shade, in composition and selection produced by artistic feeling or culture deservedly take the first rank.

5. *Scientific*.—The value of a purely scientific training to the working photographer has, in my opinion, been a great deal overestimated. In the early days of the art, when the worker had to go through a series of delicate chemical processes for each photograph

taken, and when the successful performance of these processes was alone sufficient to tax the knowledge and skill of one individual, it may have been true that a trained scientist was the best man. But, in these days of dry plates and ultra-simplified printing processes, photography, except in its purely scientific divisions, is being lifted above a test of chemical knowledge or optical expertness, and in taking its position as by far the most valuable handmaiden, the fine arts process must, sooner or later, be admitted into partnership with them.

The chief use of a knowledge of chemistry, molecular physics, and optics to the photographer, independent of the general educational value, lies in their giving him a clearer insight into the sciences he utilises in his work, and thereby inducing an interest in it which acts as a powerful antidote to the apathy which is so fatal an enemy to progress.

#### MORE CARE REQUIRED IN SPECIALISING.

Another division of his subject is recognised by the photographer more and more clearly as his work proceeds. Having probably started by associating photography with taking portraits only, he becomes conscious of fields and scope for work in which portraiture plays no part; he finds workers devoting the whole of their time and energies to landscapes, to copying, to architecture, to printing, or to process work; and even in portraiture alone he finds one worker devoting himself to operating, another to retouching, and a third to printing. He begins to realise that it is impossible for an average individual to master every branch of photography, and so it comes about that he, like the others, has to select some departments and reject others—in fact, specialise.

In doing this, he is usually guided by what he considers the most lucrative portion of the art, and in most cases portraiture seems to be chosen. It is, of course, a matter of opinion as to which branch of photography offers the most lucrative openings; but in my opinion the prospects of a landscape or general worker, or a reproductionist, at the present time, are better than those of a portrait photographer, these prospects being not so much in the silver print as in the collotype film, the copper plate, or the type block.

There are other factors also which should be considered in deciding upon the direction in which to specialise. The probationist, while it is still in his power, should be guided more by his own capacities and temperament than he is at present. If he likes indoor life and delights in the human figure, he would be unwise if he did not take up portraiture; but if an outdoor life suits his constitution and tastes, he would be equally unwise if he did not specialise in landscape or other outdoor work. For town life he must be more expert and specialistic than for country life, for which a good general excellence is better suited. And, again, according to his proclivities, he should choose the artistic or manipulative sides of his subject.

Whatever special branches he ultimately adopts, a good general and art education, and a good technical and trial knowledge of all the principal photographic processes, with their individual applications and possibilities, should form the basis of his work.

#### EVIDENCE OF THE PRESENT INSUFFICIENCY OF TRAINING.

Evidence of the insufficiency of the present system of photographic training is everywhere present in the extremely limited range of most workers' manipulative skill, which, while good in itself when carried to sufficient perfection and supported upon a general foundation, is frequently mere rule of thumb, so that the results are capricious, and, in taking up new processes or methods which the progress of technology or discovery may render advantageous the worker finds himself but little better than a novice; also in the deficiency of technical, artistic, and general knowledge so commonly met with, which, while it is excusable among those who, interested in photography, are not expected to know its *minutiae*, it is inexcusable among those who are supposed by their calling to have been properly educated in the art they profess; and, last but not least, in the surprising facility with which a determined outsider will place himself on a level with workers of a lifetime.

#### A REMEDY.

It is, I believe, in the spread of a sound and largely extended intermediate or supplementary training to that of the school and the studio that the photographer will not only occupy an impregnable position as a specialist, but will also learn how to utilise to the *utmost advantage* the factors and processes at his disposal, and in so doing will both kill the unskilled competition from which he in so many cases at present suffers, and will place his business on the soundest of all foundations.

Mr. F. R. Tissington is the Hon. Secretary of the Polytechnic Photographic Society, and all letters should be addressed to him at 309, Regent Street, W.C.

Mr. Michael A. Scott, of 2, Victoria Crescent, Obau, N.B., has withdrawn his dark-room from our register. Our readers will please make the necessary correction in our "Annual."

# THE IMPERIAL PLATES

---

SPLENDID QUALITY!  
POPULAR PRICES!

---

THOS. BEDDING, Esq. (British Journal of Photography), writes.

*"I am charmed with your Plates."*

---

Sample box of One Dozen  $\frac{1}{4}$  or Half-Dozen  $\frac{1}{2}$  Plates, 1s., sent on receipt of remittance.

---

## THE IMPERIAL BROMIDE OPALS.

Finest and Best.

Rapid and Slow.

Same Prices as our Extreme Rapidity Plates. Sample  $\frac{1}{2}$  doz.  $\frac{1}{2}$  Plates 1/6 post free

---

## Our Thickly Coated Landscape Series

ON SELECTED GLASS.

Same Prices as our Extra Rapid Plates. Sample Dozen  $\frac{1}{4}$  Plates or Half-Dozen  $\frac{1}{2}$  Plates 1/3 post free.

## PHOTOGRAPHY:

Its History, Processes, Apparatus, and Materials: comprising Working Details of all the more important Methods.

By A. BROTHERS, F.R.A.S.

GENERAL CONTENTS:—Part I. Historical Sketch; Chemistry of Photography; Optics of Photography; Light in Photography.—Part  
II. Processes.—Part III. Apparatus.—Part IV. Materials used in Photography.—Part V. Applications of Photography; Practical Hints.

\*\* The Volume is fully illustrated with Twenty-four Full-page Plates by the different processes described, and contains  
many Tables and Woodcuts in the Text.

"A most comprehensive volume. . . . The PRACTICAL HINTS are of GREAT VALUE."—British Journal of Photography.

"Certainly the FINEST ILLUSTRATED HANDBOOK to photography ever published. . . . SHOULD BE ON THE REFERENCE SHELVES OF EVERY PHOTO SOCIETY."—  
Amateur Photographer.

A FULL PROSPECTUS ON APPLICATION.

London: CHARLES GRIFFIN & CO., Ltd., Exeter Street, Strand.

# How to Make a Set of Photographic Apparatus.

By H. J.

## CHAPTER I.

### A SINGLE EXTENSION CAMERA.

IN these papers I shall endeavour, as far as possible, to give plain and simple instructions so as to enable any and every one who can handle tools (and there are very few who cannot do so, more or less), to make a good, strong, and serviceable set of apparatus; and while a certain amount of brass work is absolutely necessary, I shall recommend it as little as I can, for two reasons; one is, brass work is very expensive, and the other, it requires skill to fix it properly, and also adds weight to the camera; and though some may think that a camera looks best when covered with brass, I do not think so myself, and therefore I say, do without it as far as you can.

A few hints as to the manner of preparing the wood will not be out of place here, and these will apply to the whole series of papers. Where practicable, the wood should be prepared in a long length—as, for instance, for the camera body, for dark slides, &c.—and cut off in lengths afterwards. When the wood is first obtained it will most likely be in the rough; now choose the best side and plane it smooth, straight, and out of twist; then mark this side and square

FIG. 1.

one edge from it, making it also quite straight and true. Now it is from this side and edge that all marking and squaring must be done, and the other side and edge must be also marked with a gauge from these two, and when planed to the marks the piece will be found absolutely true in every way. Strict attention to these particulars will cause better work to be done than would be possible otherwise; indeed, it is inattention to these small details which is the principal cause of the difference in amateur and professional work.

Having said so much by way of general introduction to the whole series of papers, I will now proceed with the one in hand. First as to the wood required; this should be well-seasoned mahogany, and if you can get a part of an old piano or bedstead or anything that has been made a few years, do so, as it will be better wood and also better seasoned than is possible to buy new; but if old cannot be obtained, then we must manage with new. It should be cut out to the various sizes required, and stood about in the sun a few days before working up, when it will be fit for use. All the sizes I am about to give are for a half-plate camera, which is the size

I should advise you to make, as the fittings will cost but very little more than for quarter plate, and, if required, you can still use the smaller plates in the large camera. The brass fittings should be obtained before commencing to make the camera, as you can then fit them as you go on, and the bellows as well; these can be obtained from many makers, but some are much dearer than others. I therefore give a list of fittings below, with the prices they should be, and if anyone fails to obtain them at that price, I will do

FIG. 2.

so for them if they will send remittance and postage. This I offer to do simply to oblige, as I would rather each one got them for himself.

	s.	d.
Focussing screw, complete .. .. .	3	0
Hinges for baseboard, sliding piece in ditto, and focussing screen .. .. .	1	6
Side stays and screws to front .. .. .	2	0
Fittings for swing back complete .. .. .	3	3
Brass strips to hold dark slide .. .. .	1	3
Reversing back fittings, and stops for focussing screen .. .. .	1	8
Plate and screw for rising front .. .. .	0	9
Brass screws for the whole .. .. .	0	7
	14	0

Leather bellows, 6s.; or cloth bellows, 4s.

The above fittings are finished and lacquered and the leather bellows varnished, which you should see is done with all fittings you buy.

FIG. 3.

And now I will suppose that both wood and fittings are ready, therefore we can commence to make the camera. The baseboard will be the first to make; this is shown in plan in fig. 2, and a section of it, on line AB, is shown in fig. 3. The full size is  $8\frac{1}{2}$  in. wide by  $10\frac{3}{4}$  in. long; so first prepare a piece of board of that size and quarter inch thick, with the grain running crosswise, that is in the direction of the arrow in fig. 2; now make a piece of the section shown by shaded portions in fig. 3, 22 in. long, and when made cut it in the middle (I should have given the size; it is  $\frac{3}{4}$  in.  $\times$   $\frac{1}{2}$  in., the rabbet being  $\frac{3}{16}$  in. each way),

and screw and glue one piece along each side of the above piece as shown in fig. 3, keeping the screws even distances apart and in a straight line, so as to give it a neat appearance; these two pieces are marked G on the plan, fig. 2. Now make the piece H, and fit in between the others; this will be the same size, but will require no rabbet, but must be fitted neatly in the rabbets of the side pieces and fixed with glue and screws in the same way; the piece I can also be fitted but not fixed yet. Now

FIG. 4.

make the sliding piece K, figs. 2 and 3; this must be the same thickness as the side pieces, and 2 in. wide, and fitted so that it will slide easily in the rabbets of the side pieces, but must not be loose enough to move sideways. This piece can now be held close to the end of baseboard (H), and a mark made across the whole,  $2\frac{1}{4}$  in. from the end; then let in the baseboard hinges and also the hinges of sliding piece as shown, keeping the round joint of hinge downwards and the centre of hinge just on the mark drawn across. The hinges having been fitted and screwed on, take them off again, and with a fine saw cut through the baseboard, and, taking off a shaving or two, to make the joint smooth, it will be ready for putting together again, but before doing this, let in the threaded plate of the focussing screw into the edge of the narrow part of sliding piece, and cut a slot for passage of screw through both parts of same piece from the bottom, that is the side away from the hinges. Now screw on both pairs of hinges again, and the baseboard can be laid on one side while the other parts are made.

FIG. 5.

The camera body can now be made; this, as will be seen in fig. 1, is made up of three parts, marked B, C, and D, and are the front, back, and swing back respectively. As all three have to be alike, it is the best way to make them all in one, and cut them apart when made. We shall therefore want a piece of wood 3 ft. long, 2 in. wide, by  $\frac{3}{8}$  in. thick. This is the size after it is planed up. A rabbet must be run along each edge, as shown in fig. 7 (which is a section of the finished wood),  $\frac{1}{4}$  in. deep, and on half the thickness of the wood. This can now be cut into four pieces, and put together as shown in fig. 8, making it exactly  $8\frac{1}{2}$  in. square outside. It would be a better plan to dovetail it together; but that requires some skill to do it properly, and I shall show how to do it in my paper on a long-extension camera, so that those who wish to dovetail it have only to wait a week or two and they will see the

way to do it; in the meantime the method shown will answer the purpose very well, and is much easier for unskilled hands. Before putting the body together, set a gauge to  $\frac{5}{8}$  in., and mark all the pieces from one edge, then alter the gauge to  $\frac{1}{2}$  in., and gauge them from the other edge. These marks are shown in fig. 7, but of course they will be on the sides of each piece, and will be guides for the screws which fasten the body together; otherwise, if the marks were not made till it was finished, you might find that you had to cut through a screw or two. Do not omit to use glue, as well as screws, in putting the body together. After the glue has set, cut along each gauge-mark with a very fine saw, and just take a shaving off each part, so as to make it smooth, and, if you can manage it, run a small bead all round both edges of the middle piece C. This will give a finish to the camera when put together.

The front or widest outside piece can now be fixed to the front of the baseboard, keeping it just flush all across, the easiest way to fix it is by screwing from the inside of the front into the baseboard; two screws will hold it. You can now fix the bellows to this piece; that is done by glueing the front of bellows, and when placed in the frame B in their proper position, screw small strips of wood all round. This is better than trusting to glue only. Now draw out the sliding piece K, which can be done by first removing the end I, which I told you to leave unfixed, and fix the

FIG. 6.

middle part of body to the wide part of the sliding piece, keeping it just level with the extreme edge, so that when the sliding piece is pushed as close as it can go to the end of baseboard the two parts of body will be together the same as they were before cutting apart. The fixed plate of focussing screw must now be fitted into the end piece I, and the screw itself cut to the proper length, which is so that it will just take hold in its nut, when the sliding piece is as far back as it will go. Now place the end I in its place, and turn the winch handle, when it will draw the piece C smoothly and easily up to the back end of baseboard, and if it works rightly the end of baseboard can be fixed in its place in the same way as the other end was, but *without*

FIG. 7.

glue, as it might be wanted to take it out again at some time. The remaining part of the camera body can now be placed at the back of the others, and the other end of bellows fixed in it in the same way as the other was in the front, but whereas the other is hidden, this will be in sight when the reversing back is off, so care must be taken to put the strips of wood which hold the bellows in neatly. The front part of camera can now be finished. To do this first fit a piece of wood, deal will do, into the rabbet

which is all round the front piece B; this can be fixed in with screws, and must have a hole about 4 in. high and 2 in. wide, in the centre. This, as will be seen, is for the lens, and the extra size in height is for the rise and fall of front. The thickness of this false front should be  $\frac{1}{4}$  in., so that it just fills the rabbet, and this being fixed the real front can be made and put on. To make this, prepare a piece of  $\frac{1}{4}$  in. mahogany,  $9\frac{1}{2}$  in. long by  $6\frac{1}{2}$  in. wide, gauge it up exactly parallel, and run a small rabbet down each edge *on the front*. Then prepare another piece  $1\frac{1}{4}$  in. wide and double the length of the other, and run a similar rabbet down one edge, *on the back*. The other edge of this piece can be rounded, and then cut the piece in the middle, and screw one piece up each side of the front. The wider piece will then slide up and down in the grooves formed by the rabbets. The rounded edge of the narrow pieces will form beads, and will look better than though it was left square. The slotted plate can be let into the front, and a plug-nut inserted in the false front, so that a milled head screw will hold the front in any position. The front, complete, is shown in elevation at fig. 4, and in section at fig. 5.

FIG. 8.

The hole for lens had better be left until you get your lens, and then cut it to fit.

The front stays can now be fixed. This requires no explanation, as they simply want screwing on, and the nuts inserted in their proper place, one to hold the camera open, as in fig. 1, and the other at the top when the camera is closed, the stay having a hook to engage with either one or the other as required.

We now come to the swing-back fittings, which are also easily understood without explanation, the plates being fixed to the swing back, and the nut of screw inserted in the other part; the back will then swing either way and will be fixed by a turn of the milled head.

The reversing back is the next part to proceed with. An upright section is shown in fig. 9. First prepare a piece of  $\frac{1}{4}$  in. mahogany, and make it so that it will fit closely in the rabbets at back of camera, that is, in the swing back. Now cut out a piece  $6\frac{1}{2}$  in.  $\times$   $4\frac{3}{4}$  in. out of the centre, the  $6\frac{1}{2}$  in. way being *across* the grain. Then prepare a piece 18 in. long,  $1\frac{1}{4}$  in.  $\times$   $\frac{1}{4}$  in., and rabbet it on  $\frac{3}{8}$  in. and  $\frac{1}{16}$  in. deep; it will then be of the same section as shaded portions in fig. 9. Now cut the piece in two, and screw one part of it on each edge of the other piece, overhanging nearly a quarter of an inch. These pieces must be fixed parallel with the long way of the hole cut out of first piece. Brass strips can now be screwed in each of the rabbets, as shown in section (fig. 9). These form the grooves for the dark slide to run in, and the brass could be dispensed with by forming the grooves in the wood, but I consider the brass is stronger, and the slides work better and with less friction, but you can use which you think best. The two clips can now be screwed on at one side and the two clip hinges at the other, fixing them so that they will hold the reversing back close in without being too tight so as to damage it, or so loose that it will drop off by itself.

The focussing frame will now finish the job. This is simply a frame fitting between the two brass strips, and finishing off level with sides of camera. It must be made with an opening of the same size as that in reversing back, and corresponding with it in every way, and a rabbet must be formed round the opening to hold the focussing glass, but this had better be left until the dark slides are made, as the surface of glass must be exactly in the same plane as the surface of sensitive plate in the dark slide; but as the

focussing frame belongs to the camera I can give instructions for making and hanging it here, and it can be referred back to afterwards. The frame can be prepared in one length and mitred at the corners, the surplus wood on the long sides being taken off when it is finished. A small key can be put in to strengthen the mitres, but this I shall describe in the dark slide making, so it is no use doing so now. The focussing glass is held in frame with the four corner pieces, as shown in fig. 6, and is hung with double-jointed hinges and fastened with a turn-button at bottom, as shown in same figure.

A small hook and eye can be put on top of camera to hold it together when folded, and a handle for carrying, and the camera is done "except finishing," as they say. To finish it, take off all projecting brass work, and first give the inside woodwork a coat of dead black, which can be obtained for sixpence with the brass work, then rub over the outside of all woodwork with fine glass-paper, and rub in a little linseed oil. When this is well dried in, take a piece of wadding or cotton wool and roll it into a ball, cover it with a piece of old linen, and drop on it a few drops of French polish, and rub it all over the woodwork, using more polish as the rubber gets dry. When you have got a fair polish on it, stand it on one side for a day, and then go over it again, and finish off finally with a little methyated spirits instead of polish on the rubber, but be careful and do not let the rubber rest on the polished surface, always keep it moving.

The brass work can now be replaced and the camera is finished, and for use and looks will bear favourable comparison with any in the market at three times the amount it has cost to make it, reckoning nothing for the time of making, of course.

I shall in my next paper give instructions for making a double extension camera.

If there should be any detail which I have not explained sufficiently, or which seems difficult to understand, I will do my best to make it clear, on your wishes being made known either through the columns of the AMATEUR PHOTOGRAPHER, or by letter through the Editor.

FIG. 9.

#### EXPLANATION OF DRAWINGS.

- Fig. 1. Side elevation of camera.
- " 2. Plan of baseboard.
- " 3. Section of baseboard on line A B.
- " 4. Front elevation of camera.
- " 5. Section of elevation on line C D.
- " 6. Back elevation of camera.
- " 7. Section of camera body before cutting.
- " 8. Method of joining body at corners.
- " 9. Section of reversing back.

#### REFERENCE TO LETTERS.

- A. Baseboard.
- B. Front part of camera body.
- C. Back or middle part of body.
- D. Fixing back.
- E. Guide strips for dark slide.
- F. Focussing frame.
- G. Side stays.
- H. Front end of baseboard.
- I. Back end of baseboard.
- K. Sliding or focussing piece.
- L. Side strips to front.
- M. Rising front.
- N. Clips and clip hinges to hold reversing back.
- O. Brass strips to form grooves for dark slide.

The same letters refer to the same parts in all the drawings.

(To be continued)

## Photography by Rule.\*

### A RETROSPECT.

TEN or twelve years ago, when the gelatine dry plate had finally conquered the prejudice of professional photographers, and the ranks of amateurs were being swollen by the accession of many to whom wet-plate photography was unknown except by name, it was often charged against photographers of both classes that their work was largely governed by "rule of thumb"—in other words, that in exposure and development, probably the two most important divisions of photography, success was allowed to depend very much upon pure guesswork, in contradistinction to system and calculation. Those were the days when the rapidity of the plate was generally under-estimated; when a frequent if not common method of compounding the developing solution was by shaking an unknown number of grains of dry pyrogallie into an unmeasured quantity of water, and, after soaking the plate in it, adding thereto an undetermined number of drops of ammonia. For rapid exposures, a simple drop shutter, whose rapidity of action could easily be accelerated, but was rarely if ever reduced to arithmetical expression, was mostly used; and albumen paper held practically undisputed sway for contact printing. These broad outlines of early gelatine dry-plate photography may, perhaps, serve to convey some idea of the chief conditions of working which obtained at that period—conditions under which, be it remembered, amateurs as well as professionals pursued photography.

It is, I am sure, needless for me to indicate precisely to what extent those conditions have been changed or modified, for you are all aware that development has been lifted from the low ground of a "rule of thumb" operation to the level of a scientific study; the comparative and particular speeds of sensitive preparations have been made the objects of close investigation and valuable experiments, and mechanical aids to exposure have called an apparently inexhaustible supply of inventive ingenuity into existence—the main and indeed the sole object underlying all those efforts being not merely the simplification of exposure and development, but their reference to pure rule and system. I propose briefly on the present occasion to consider some of the tendencies of modern photography—chiefly amateur photography—for which the application of this scientific method to several of its branches is responsible, and to submit a few reflections of a deductive character thereon.

### RULE OF THUMB.

Before dealing with that part of my subject, however, I wish to submit that the bad old "rule-of-thumb" days of gelatine dry-plate photography do not expose a very broad target for the arrows of our reproaches. Point to point, and excluding from consideration the well-directed but unconvincing productions of the new diffusion-of-focus school, a comparison of amateur and professional photographic work of twelve years ago with that of to-day reveals little, if anything, in favour of the latter. The portraiture of professional photographers is possibly, on the whole, more instinct than formerly with artistic feeling and treatment; but that is not a matter upon which I wish now to descant. It is from a technical standpoint alone that I desire to make the comparison. My own observations lead me to think that, technically speaking, in qualities of negatives and prints, the professional work of to-day is practically what it was a dozen years ago, taking it at both its best and at its worst. The negatives of the former period were, perhaps, not so pretty and clean to look at as those produced nowadays; but will anybody undertake to say that the resulting prints exhibit any traces of inferiority to those at the present time—that the negatives were not so well exposed, or that the prints were inferior in point of careful printing, uniformity, and depth of tone? The same question stands for all other kinds of professional work—always remembering that I wish it to have a technical bearing and no other. It is, of course, not so easy to make a comparison of amateur work, because in the times I am referring to, exhibitions were few and far between; but recalling the pictures shown at Pall Mall and elsewhere at that period, and contrasting them with those of to-day—a mental process in which, no doubt, most of you can accompany me—I fail to perceive that any distinction is to be made. Technically speaking, the work shown then was quite the equal of that shown now, and probably the average of quality was higher.

\*Read before the North Middlesex Phot. Soc. by T. Bedding.

I have roughly traced the conditions under which photographers—amateur and professional, new and old—formerly had to work. Recollect also that failures were more frequent then than now. Dry-plate making was in its tentative stage, and, consequently, to the difficulties of exposure and development a large number of troubles incidental to the preparation of the film—such as are not often experienced nowadays—had to be habitually encountered. Those were the times of constant frilling, of red and green fog, and of numerous mechanical imperfections in the films; and the percentage of failures was, consequently, high. Yet, notwithstanding these obstacles and drawbacks; notwithstanding unscientific rule-of-thumb methods of exposure and development; notwithstanding a condition of knowledge of applied photography such as many to-day might be inclined, with their superior advantages, to stigmatise as ignorance, we have not, I submit, made any technical advances on the productions of that time. Tastes and fashions have changed in respect of new developers, printing surfaces, and so forth; but a change does not necessarily lead to an improvement in intrinsic quality.

### A PLEA FOR TECHNICAL EXCELLENCE.

Do not, however, suppose that I am not alive to the economical advantages of the improved developers with which we are working; of film photography, of the value of orthochromatic plates for certain classes of work, and of the remarkable cleverness displayed in countless shutters, hand-cameras, and so forth. Each of these has its uses according to individual idiosyncrasies, but, if I am correct in my suggestion that in technique photography stands to-day where it stood at the commencement of the last decade, their introduction was not called for by necessity, and their existence is not essential, and has hardly been justified by results. I am unable to understand that they have improved the technique of photography. Technically good photographs, I venture to think, are not so prevalent that we can afford to regard them with the contempt bred by familiarity. At a moment when the art aspects and attributes of photography occupy so much attention, perhaps a plea for technical excellence may not be misplaced. While I have, I hope, as keen an appreciation as any one not an artist of what is artistic in photography, I am equally ready, and I trust capable, of appreciating what is technically good in any photograph, whether it makes pretension to being a work of art or not. Definition, however finely rendered, appeals to my sense of the fitness of things in the contemplation of photographs of architectural subjects, and I am unregenerate enough to prefer it to fuzziness in landscape work, with or without figures. Definition, or sharpness to a refined degree, is in practice not so easily or invariably obtained; a photograph is not so frequently taken from the correct or the most favourable point of view; distortion and other optical imperfections are not so often absent as the critical might desire; the negative is not always so carefully exposed and developed as to secure all the detail and the gradations of the subject; the printing process chosen does not so often do credit to the discrimination or the selective faculties of the photographer; and the resulting print does not so often embody the essentials of what a good print should be, that we can afford to treat excellence of technique with indifference when we meet with it. A perfect photograph of even the most commonplace object is, I consider, a tribute to the skill of the photographer, and from a technical point of view is just as calculated to evoke the admiration and the approval of photo-technologists as an art-photograph is that of an art-photographer. A line drawing to scale of a great public building by an architectural draughtsman has certain elements and qualities in it which appeal to the cultivated perceptions of an architect. Your artist may sneer at its "mappiness," but he dare not and cannot impugn its proportional accuracy and its fidelity. On the other hand, when the artist idealises the same building in his painting, how easy it is for the architect to discover faults of perspective, proportion, and drawing! At the Royal Academy there is (or was) a room devoted to architectural drawings, and, I believe, it is on record that some years ago some such disparity as that which I am now hinting at was pointed out and commented upon.

### THE FOCUSING SCREEN THE BEST ACTINOGRAPH.

Heretical though it may sound, I do not think that the cause of photographic technique is in the least likely to be advanced by the present disposition, especially among amateur photographers, to base the making of the photograph as much as possible upon

[AN UNSOLICITED TESTIMONIAL FROM AN AMATEUR OF  
**22 YEARS' EXPERIENCE.**

To Messrs. ELLIOTT & SON,

BARNET, HERTS.

"Dundrennan, Kirkcudbright, N.B.,  
 23rd April, 1892.

"DEAR SIR,

I yesterday effectually tested a packet of your **Ordinary Barnet Plates** upon Landscape subjects. I used Drop Shutter on every plate, single Landscape Lens, Stop  $f/16$  light good, and

**DID NOT MISS A PLATE, ALL GOOD,**  
 and without doubt after the full **experience of 22 years** I have no hesitation in placing the **BARNET PLATE** in the very front rank, as a **quick, clean, and easily developed plate of the HIGHEST ORDER.**

"Yours faithfully,

"J. COPLAND."

## UNSOLICITED TESTIMONIAL.

2, ST. MARY'S ROAD, CANONBURY, N.,  
*July 14th, 1892.*

Messrs. MARION & Co.—Gentlemen,

I have been trying your three qualities of Plates—Ordinary, Rapid, and Instantaneous—on a variety of out-door subjects, in bright and dull weather, being guided as to exposure by the new Actinograph (Hurter & Driffeld's Patent), and “speed” marked upon the packages. As the result I find the system uniformly successful, for I have not lost a single plate.

Yours very truly,

JOHN SPILLER, F.C.S., F.I.C.

MARION & CO., 22 & 23, Soho Square, London, W.

rule and system. The rule of thumb and pinch of pyro days of photography are, perhaps, over—thanks, not I believe, to formula-mongers and mechanico-arithmeticians, but to the fruits of experience and experiment. I consider it an unfortunate thing in several respects that there are so many inducements to modern amateur photographers to attempt the acquirement of a sound photographic judgment by other methods than that of simple experience. Let me cite, in point, those so called aids to exposure, actinographs, actinometers, and exposure-meters, as calculated rather to prevent the cultivation of individual judgment than to foster it. You must remember that professional portraitists and landscape-workers, and the old-style amateurs, of whom I have already spoken, relied upon experience alone to guide them in their exposures. My own belief is that a man who takes up photography will surmount the difficulties of exposure by the aid of his own brains, or not at all. If he has not brains enough for that, then he is equally incapacitated for mastering the philosophy of exposure calculators. I am about to examine some of the principles upon which actinometrical or actinographical systems are based, and possibly to draw some conclusions not entirely favourable to them; but, before doing so, there is one exposure-meter which I must exempt from objection. Indeed, I recommend it to each and every one of you. It is, I think, the cheapest and most efficient on the market, does not get out of order, if destroyed may be easily replaced, requires no arithmetical calculations to use, and may be had of all dealers. It has been testimonialised by the most successful photographers throughout the world, and, when once its application is mastered, it seldom leads you astray. With it all the best photographs have been taken, and thus, in regard to medals, it, as our friends at Ilford would say, has secured more than all the rest. It is an exposure-meter which enables the photographer with brains enough to use it to get twelve good negatives from a dozen plates. No photographer should be without it, and no photographer is. Need I say, gentlemen, that I allude to the focussing screen of the camera? It is by the study of the image on the screen, it is by comparing the depth of the shadows, the strength of the half-tones, the brilliancy of the high lights, with those of other pictures taken under similar circumstances; it is by studying the visible influence of the lens diaphragms on the brightness of the image; in short, by comparing the exposure about to be given with that previously given under similar or different conditions, as the case may be, that experience was gained in former times. It is theoretically a very unscientific method, of course, but you all know how well it has answered practically. Occasionally it fails; but can you conceive of an infallible actinograph? Besides, it is good that it should fail at times for what an education in development under and over exposure provides for the painstaking photographer, who is willing, as he should be, to learn from his failures! You may say to me that these last advantages also accrue to the employment of an exposure-meter or an actinograph? Granted; but in that case why use an exposure-meter or an actinograph? An instrument or system of this nature, plus an unerring judgment of those factors in exposure compulsorily left to the estimation of the individual, and which is fallible, seems to me not to possess any point of superiority to the unaided fallible judgment alone. I shall endeavour to show that the probabilities of any instrument or system for indicating correct exposure can scarcely be other than incorrect; to the contrary of which there are practical objections which science is, I believe, powerless to overcome.

#### NO EXPOSURE FACTORS "CONSTANT."

Mr. Howard Farmer recently pointed out that several important factors are not taken account of in certain systems of calculating exposures; but, even if the omitted factors—such, for example, as colour and distance of object—were included, I will submit that theoretical or practical accuracy could not possibly be assured. To the inexperienced or the beginner in photography, for whom, bear in mind, all these aids or guides to exposure are intended, the difficulty of estimating, or, rather, of judging the actinic value of the light on any day or at any hour is no considerable one, especially if you reflect that even a photographer of ripe and lengthy experience is occasionally mistaken in his judgment. I have seen it stated that of the three principal factors involved, viz., the light, the speed of the plate, and the aperture of the lens, the two latter are constant. But the ascertained comparative or particular speed of a plate so soon as it leaves the manufacturer's drying-room does not appear to be above

suspicion of change. Quite recently, Dr. Vogel, of Berlin, gave instances where commercial plates materially increased in sensitiveness after a month or two's keeping, and the same phenomenon has been claimed to have been observed by several other workers during the last few years. On the other hand, some photographers have concluded from the results of experience that sensitiveness diminishes by keeping. If either of these two theories is correct, the speed of a plate, no matter how it is ascertained, cannot be reasonably accepted as a constant factor in exposure calculations. Again, the argument, in reference to the aperture of the lens, that all lenses are of equal rapidity with a given stop, assumes two conditions which are far from being always realised, namely, that the diameters of the stop openings are accurately expressed in relation to focus, and that all lenses are on an equality as to the amount of light they pass. Optical glass, however, is, I believe, of somewhat varying quality as regards colouration, experiment having proved that even in modern lenses as much as twenty-five per cent. of the light is occasionally obstructed by the colouration of the glass as compared with the glass employed in other objectives. One can easily understand that time superinduces changes in the glass of lenses as well as in the material with which they are cemented so as materially to slow them. Can it, then, be fairly claimed that all or either of the three factors I have referred to are to be accepted as constants in basing calculations upon them? If so, in what manner will you dispense with individual judgment if you admit, as you must, the no less important factors of colour and distance of objects to your calculations? I put it, that constancy of any of the factors in exposure calculations is far from being the certainty we are asked to believe.

#### "FORMULÆ."

That exposures calculated according to the systems we are now discussing are sometimes correct, I do not deny; it would be strange were it not so. But an exception does not negative a principle, and it is a principle I am urging, namely, that of buying photographic wisdom by photographic experience. The world's photography has so far been accomplished by the aid of the actinometrical readings of the focussing screen; why, then, should the beginner or student expect to extract from mere empiricism the knowledge which has been shown to result from the reliable, although unscientific, method of trial and error? The plethora of new developers, the legion of hand-cameras and rapid shutters, the numerous exposure systems, seem to me to be the articulate expression of a wish to compress photography, taking into a rule-of-three sum, and so to enable one to run without the necessity of having to learn to walk. Do not understand me as advocating rule of thumb; I am merely advocating the exercise of the individual intelligence as opposed to falsely inspired formulæ. The word formulæ here induces me to recommend to you a source of instruction as to the wide range in difference of opinion which prevail among dry-plate makers and dry-plate users in respect of the proportional constitution of developing formulæ. Make a collection of such formulæ from representative sources, and convert them either into parts per thousand or grains and minims per ounce, and you will assuredly have a most bewildering statement of proportions of accelerator to reducer, and of restrainer to both, together with a lengthy list of ingredients which appear in some formulæ and not in others, and the exact functions of which many people would find it difficult to define. In the normal developer for A's plates, for example, you may see one and a half grains of pyro, eight of sulphite, and ten of sodium carbonate to the ounce; in B's developer the quantities doubled; in C's one constituent quadrupled and another halved, while in D's the inter-proportions suggest nothing so much as the constituents having been selected purely by haphazard. The curious part of the matter is, that in all probability A's developer will develop C's plate perfectly, and D's B's, and so on; in short, each or any one of the many developers you analyse, although specifically recommended for one brand of plates, will develop any other brand equally well. So much the better for the users of gelatine plates, you will say, and I endorse the sentiment, but do not overlook the obvious point, and that is that after all the years during which "scientific development" has been preached, practically the old rule of thumb still survives, and that, on the whole, photography is little the worse for it.

#### "PHOTOGRAPHY MADE EASY."

The commercially created and fostered tendency among amateur workers to substitute for the mellow judgment of experience and unwearying practice the ephemeral wisdom of the many aids to

easy photography which shrewd men of business are always anxious to supply on demand, tends, in my humble opinion, to undermine those valuable characteristics of practice, patience, application, self-reliance, and perseverance which have hitherto been recognised as essential to the making of the successful photographer, amateur or professional. Frankly speaking, I look upon it as one of the causes to which we may refer the admittedly low average of quality of modern amateur work. The best amateur work of to-day is undoubtedly as good as, and possibly better than the work of ten or twelve years ago; but the average strikes me as lower, an opinion which I base on a comparison of the work shown on the walls of exhibitions during that time. Probably the seductive simplicity of the hand-camera and the fascinating facility of shutter work have also operated in the same direction.

In conclusion, I renew the plea I have already entered for technical excellence of photographic work, for technical skill in producing it, for technical instinct in appraising it. But the excellence, the skill, and the instinct can only be reached by assiduous cultivation. Believe me, while there are many persons to whom a photograph is only admissible when it appeals to their æsthetic emotions, there are probably a far larger number who, while ready to welcome the artistic effects produced by "diffusion of focus" and low-keyed tones on rough surfaces, have a far higher appreciation of the technical qualities previously referred to. Whether or not the cause of technical photographic excellence and progress is likely to be promoted by the attempts now being made to convert photography into an involved arithmetical exercise, and, in fine, what the tendencies of that movement are, is a point for discussion that I have endeavoured to lay bare to you in the course of a series of intangible generalisations and impressionistic reflections which, I hope, while blunting the edges of your critical dissecting knives, have not wholly undeserved the attention you have been so good as to bestow upon them.

## The Theory of Development.

NOTES ON PROF. H. E. ARMSTRONG'S PAPER,

By H. M. ELDER, M.A.

The paper read by Prof. Armstrong at the last Camera Club Conference, with the exception of a paper read by Mr. Bothamley at the Conference three years ago, is the first attempt that I have seen in print to apply some of the modern views of chemical action to questions of photographic chemistry. According to these views, chemical change is looked upon as conditioned by the energy relations of the substances undergoing change. This being so, I hope I shall be excused if I say a few words about the objects aimed at and the results obtained by this method of looking upon chemical change.

It was in 1867 that the Swedish chemists Guldberg and Waage published their great paper entitled, "*Études sur les Affinités Chimiques*." In this paper they considered the effects on the course of a chemical reaction of variations in the quantities of the re-acting substances in any given volume, that is, of the concentrations of the substances. They enunciated the law that the speed of chemical change, or the number of equivalents undergoing change per unit time, is, other things being equal, proportional to the concentration, or, as they call it, the active mass of each of the substances taking part in the change. They devised experiments to verify this principle on two lines. In the first place they considered a reversible reaction, such as has been well described by Prof. Armstrong, in which a state of equilibrium had been attained, and no further change was proceeding. They pointed out that such equilibrium must be looked upon as due to the simultaneous occurrence of equal and opposite changes, or of changes the speeds of which were equal. By the application to such a system of the law mentioned above they were enabled to find numerical relations between the concentrations and the tendencies to change of the bodies concerned. In the second place, they considered the speed of a reaction in course of progress, and were thus enabled to find relations between the tendencies to change or co-efficients of affinity of various bodies. In 1865 and 1866 a somewhat similar view was put forward in two papers printed in the Philosophical Transactions of the Royal Society, by Messrs. Harcourt and Esson. These papers contain a very complete discussion of two cases of chemical change considered from the second point of view, and an enunciation of practically the same law. Since this time Ostwald, Potilitzin, and others on

the Continent have done much valuable work in this direction by various methods.

The result of all their researches is to confirm the laws enunciated by Guldberg and Waage, which may shortly be stated as follows:—The speed of a chemical action is, other things being equal, proportional to the active masses of the bodies taking part in the reaction. It also depends on the presence of other bodies, each of which exerts its specific influence in proportion to the quantity present, and on any subsidiary or secondary reactions that may occur. The active mass of a reacting body is in general proportional to its concentration, but if any of the substances taking part in the change are immiscible with the rest, the active masses of such substances may usually be taken, at least approximately, as constant.

To take Prof. Armstrong's paper in detail would involve a very lengthy discussion, as there are so many points of great interest referred to, on each of which there is a great deal to be said. I will, therefore, only consider a few of the questions raised.

In the prologue of his paper, to use Prof. Armstrong's own word, he advocates the consideration of the changes that take place in development from an electrical point of view, and from a paragraph later in the paper I gather that he would look, as it were, through electrical spectacles on the changes produced by the action of light. Now, with all deference, I would submit that not much, if anything, is to be gained by taking this point of view. In fact, I think that it distinctly increases the already great difficulties that meet us. It is, of course, a truism to say that electrical action always occurs with chemical change, and that there is an electric current set up in some circuit, molar or molecular; and in the case of measurable circuits, such as are considered in discussions on electrolysis, much is to be gained by this method. But when we have to think of molecular circuits, which by no possibility can be handled or measured, the application of Ohm's law would seem to be merely the explanation of *ignotum per ignoto*; and our knowledge is not advanced by such a discussion! All chemical action, whether we consider it from an electrical point of view or not, must ultimately be explained, so far as it is capable of explanation, by dynamical considerations, and in our present state of knowledge it is far simpler to apply these considerations in a manner that is independent of the mechanisms by which the actions are brought about than to complicate matters by considering this at least partially unknowable mechanism.

There are three laws of physics that may be applied to any physical or chemical system without a knowledge of the structure or mechanism of the system. These are—(1) The law of the conservation of energy, known as the first law of thermodynamics; (2) the second law of thermodynamics; and (3) the principle of least action.

Of these the first and third are axiomatic and are universally true, while the second is a deduction from observation, and is perhaps included in the third. These three laws are purely dynamical principles, and, in my opinion, the application of them is more likely to yield good fruit in the present state of our knowledge than considerations involving an assumed knowledge of the mechanism of chemical change.

Prof. Armstrong, in the prologue to his paper, is really making use of the first of these laws combined with the second used qualitatively. But, as I have already said, it seems to me to be introducing a somewhat needless complication when he translates the straightforward expression of the tendency of available energy to fritter itself away into heat at a low temperature into electrical language, and expresses it in terms of a circuit, the electrical constants of which are necessarily unknown.

Passing on the next portion of the paper, development is considered as a reversible action, which is subject to the Guldberg and Waage laws. This may be looked upon as the application of the third fundamental principle that I have mentioned, since Prof. J. J. Thomson has been able by a course of mathematical reasoning to deduce the Guldberg and Waage laws from the principle of least action (*see* "The Application of Dynamics to Physics and Chemistry," by J. J. Thomson, chap. xiv.). It is most welcome to see an attempt to consider the chemical actions that are utilised in photography from this point of view, though we are still too ignorant of their nature to give a complete account of them. In putting forward their theory, both Harcourt and Esson, and Guldberg and Waage, were careful to

choose the simplest reactions they could find, and naturally so, as their object was to illustrate and confirm their theory. But now that the broad principles are beyond doubt, we may struggle to apply them to more complicated systems.

Before, however, considering this further, I wish to somewhat demur to an assumption which is, I think, generally made, and which Prof. Armstrong makes explicitly in his paper, viz., that the action of ammonia in the developer differs in nature from that of the fixed alkalis, because the silver haloids are soluble in ammonia. Now this is, I think, a pure assumption, and we have no proof that it is the case. The difference in result is, I think fully accounted for by the undoubted pigmentation of a pyro-ammonia developer image; and, in fact, from Mr. Bothamley's experiments described at the Conference, it seems that the silver haloids in a gelatine plate are not dissolved in ammonia of such strength as is used in developers. It is proverbially hard to prove a negative, and perhaps Mr. Bothamley's experiments are not absolutely conclusive; but, so far as they go, they show that up to the present we have no right to assume that the action of ammonia depends on its solvent powers.

[It is but right, however, to add that since writing these lines I have received strong evidence on the other side. Prof. Meldola tells me that some years ago he examined a quantity of pyro-ammonia developing solution that had been repeatedly used, and was able to find a quite appreciable quantity of silver in it.]

Let us now consider the nature of the system with which we have to deal. At any point of an exposed plate we have a certain quantity of reduction product produced by the action of light, together with unaltered silver salt and the vehicle. We may probably leave the vehicle out of consideration, as it will exert a constant influence during the progress of development. The case of a wet plate appears to be simpler than that of a dry plate. The active mass of the reduction product, which we may consider for the present purpose to be metallic silver, is probably here constant, and may therefore also be left out of consideration except as inducing chemical action. The reaction becomes simply the reduction of silver nitrate influenced by the presence of the acid restrainer, which acts in proportion to its concentration, and is what Guldberg and Waage call a "*corps étranger*." Let A stand for the number of gramme molecules of silver nitrate present in unit volume at the beginning of the reaction, B the number of reducer,  $x$  the number of molecules reduced at any time  $t$ , then the velocity of the reaction will be given by

$$\frac{dx}{dt} = C_1 (A - x) (B - x)$$

when C is a constant quantity of magnitude depending on many circumstances, among others the quantity of acid restrainer present.

The velocity of the reverse reaction will be

$$\frac{dx'}{dt} = C_2 x'$$

when  $C_2$  is another constant, and  $x'$  stands for the number of molecules of ferric salt formed in the case of ferrous sulphate development. No notice is taken here of reduced silver, since we assume its active mass to be constant, and this constant is included in C.

Development will then proceed until

$$C_1 (A - x) (B - x) = C_2 x$$

and the quantity of silver deposited and the rate of development is seen to depend on the concentrations of the free silver nitrate present and of the developer. It also depends on the magnitude of the constants  $C_1$  and  $C_2$ , in which is involved the density of the reduction product and the quantity of restrainer. It is possible to develop these equations so as to show explicitly the effect of the restrainer, but perhaps it is hardly worth while to do so now.

The case of dry-plate development is more complicated, for in this case the reduced silver is drawn from the solid haloid in the film, and we are unable to assume that the active mass of this is constant. It is, in fact, my habit to think of an emulsion as something between a true solution and a solid suspended in a liquid, a somewhat loose mode of thought I fear, but convenient. I would then think of the silver haloid in a gelatine or collodion film as possibly partly subject to some of the laws of solutions. You will easily see how enormously this adds to the difficulty of the problem, so much

so in fact that I do not intend to tackle it in the way I have indicated for a wet plate, but rather piecemeal.

The influence of the alkali in starting development is no doubt due to the positive heat of neutralisation that it possesses, but this notion fails to give any explanation of the hastening caused by increasing its strength. This, I think, must be considered, together with the influence of bromide as a restrainer. They are certainly both of the nature of mass actions. If now we write A for the initial concentration of the alkali, and B for that of the bromide, we have an equation of the form

$$\frac{dx'}{dt} = C_1 f(x') (A - x')$$

for the rate of reduction of silver haloid, or, what comes to the same thing, the rate of neutralization of the alkali.

Here  $x'$  stands for the number of molecules of alkali neutralised at the time  $t$ , and  $f(x')$  is some unknown function of  $x'$  depending on the mass action of the emulsified silver haloid.

A similar equation holds for the reverse action—

$$\frac{dx''}{dt} = C_2 \phi(x'') (B + x'')$$

At any moment the rate at which development is proceeding is the difference of these, viz., if  $x$  be the number of the molecules reduced—

$$\frac{dx}{dt} = C_1 f(x) (A - x) - C_2 \phi(x) (B + x)$$

Now if we may treat  $f(x)$  and  $\phi(x)$  as constants, viz., if we may take the active masses of the silver haloid and reduced metal as constant, which we may probably do in the beginning of the reaction, this equation becomes

$$\frac{dx}{dt} = C_1 A - C_2 B - (C_1 + C_2) x$$

which can be integrated, and becomes

$$(C_1 + C_2)x = C_1 A - C_2 B \div M e^{-(C_1 + C_2)t}$$

when M is an arbitrary constant.

This, to the best of my recollection, agrees with the results of a rough series of experiments of the slowing effect of bromide on development which I carried out about six years ago, of which I have unfortunately lost the notes.

Passing on to the next point about which I should like to say a great deal, but will spare you; Prof. Armstrong's statement as to the nature of the latent image, that he has reason to believe that there are two distinct images formed, which he calls provisionally the blue and yellow respectively, is new to me and very interesting; but one's interest would be very greatly increased if he would give the reasons for the faith that is in him. I am aware that Mr. Baker considers that he has evidence of the existence of two bodies produced by the action of light on silver chloride, and I hope that, as he is here to-night, he will tell us something about his work and the interesting results that he has obtained. But from what I have already heard from him, I do not think that his two bodies would at all answer to those that Prof. Armstrong suggests rather than describes. Perhaps, however, I am mistaken, and he will enlighten us. There is also in this part of the paper a paragraph that I hope Prof. Armstrong will explain, for I must say that I cannot in the least understand what he means by saying that the action of light is *electrolytic*, at least if the word is to be taken in its ordinary sense.

In noticing the suggestion put forward in terms of the double latent image to account for the behaviour of an over-exposed plate, I would simply remark that I did not understand from Mr. Baker that the oxy-haloid of silver was an unstable body, but, on the contrary, a most stable one. However, I hope he will enlighten us on that also.

In conclusion, I would like to make a few remarks on the phenomenon known as reversal or solarisation looked upon from a dynamical point of view. The facts as regards this phenomenon are fairly well known; our President and others after him have abundantly shown that reversal is due to a re-halogenisation or re-oxidation of the body produced in a sensitive film by the action of light, and, in his admirable "Chemistry of Photography," Prof. Meldola has attempted to work out some explanation of the reason that this takes place by the action of light alone. He concludes his speculations by the suggestion of a very beautiful analogy, in which he compares the action of light to that of a dynamo employed to charge a series of accumulators. In this

case the opposing electro-motive force of the cells may rise to such a point that it reverses the current through the dynamo, when the cells discharge only to be recharged in the opposite direction, and the same events again occur. Now the action of light seems to me to be a far more complicated matter than this, and I do not think that the suggested explanation, ingenious and beautiful as it is, will quite meet the facts.

Let us consider a sensitive plate as a system in dynamical equilibrium. There is a tendency for the silver salt to be reduced at the expense of the organic sensitiser present, which is counter-balanced by the tendency for it to be re-halogenised by the halogen compound formed with the sensitiser. As soon as light begins to act upon the plate, the factors determining the values of these tendencies in terms of the equivalent active masses of the bodies present are so altered that the silver haloid is partly reduced, and we should expect this action to continue at a speed depending upon the intensity of the light acting until equilibrium was again reached, a certain quantity of reduction product being found, and an equivalent quantity of sensitiser halogenised.

Now if we for the moment leave out of consideration any physical effect due to the vehicle, in terms of Prof. Meldola's explanation, as soon as the state of equilibrium is reached the action of the light becomes reversed, or possibly, if I may put it so crudely, the reducing action of the blue rays ceases to have any effect while the oxidising action of the red rays comes into play, the factors are again altered, and the reduced substance is again oxidised till we get a reversal, i.e., a positive image instead of a negative, when a re-reversal takes place, and so on. In terms of the Guldberg and Waage notation, if  $A$  be the number of molecules of silver haloid originally present, and  $x$  the number reduced at any time, and consequently the number of halogenised sensitiser formed, when equilibrium is attained,

$$C_1(A-x) = C_2x.$$

Now, according to Prof. Meldola, this equilibrium is essentially unstable, and when it is reached the action of the light becomes reversed just as the current in the dynamo of the analogy is, and the light proceeds to undo its former work, and to restore the original state of the plate. It is probably due to my ignorance, but I fail to see any reason for this instability and consequent reversal, and it appears to me more natural to suppose that the action would stop at this point. We know, however, that it does not, and so a further explanation must be sought. Also we know that to reach such a state of equilibrium as is here described would take an infinite time, and therefore could only be reached for any given intensity of light if the intensity varied slightly, as the current in a dynamo will do owing to unevenness in driving. If the suggestion of Prof. Armstrong, that there are two products of light action, be considered from this point of view, it will be seen that it merely amounts to a further specification of the mechanism by which a state of equilibrium is approached, and the same deadlock is reached.

The difficulty is only removed a step further by, according to a suggestion of Prof. Meldola, attributing the first reversal and re-reversal to the protective action of the gelatine hardened by liberated halogen and light on the silver salt. Besides, I have been told that M. Janssen has observed recurrent reversals in collodion plates without an organic sensitiser, though I have not been able to find the reference, and I gather from a note in one of Capt. Abney's papers in the *Philosophical Magazine* that such reversals do not occur. The protective action of the gelatine would account for a first neutral point, a reversal, a second neutral point and second negative image, with possibly a third neutral point in a gelatine plate, but seems unable to account for more reversals than this.

I should like to say much more on this subject, but I will only say further that destructive criticism is very easy, and though I fail to follow the explanations of reversal that have been referred to, I am totally unable to suggest anything better.

Finally, I would say, that Prof. Armstrong's paper seems to me to literally bristle with hints and suggestions, only a few of which I have referred to, and that I fear in a most incomplete manner, though I hope I have not laid myself open to the reproach that is often made against Shakespearian and other commentators, viz., that I have found a great deal in the paper that the author never intended to put into it. The fact is that these subjects are so interesting that one could run on for hours and not exhaust them.

## Film Enlarging by Cresco-Fylma.

A DESCRIPTION of this process was given in our issue of December 25th last. We offer in this number a few hints that may prove acceptable to our readers.

The amount of extension can be controlled by alterations in our developer. Briefly stated, the stronger the accelerator and the quicker the development, the smaller the enlargement gained, until, when we come to a forced and yellow film, the amount of enlargement is considerably reduced, besides getting a curl in the film.

We will start by assuming that hydroquinone is used as developer, and hydrate of potash or soda is used as accelerator; possibly the enlargement is not so great as desired. The remedy is to reduce the amount of hydrate, substituting some weaker alkali such as carbonate of potash, and developing more slowly. On the other hand, if the films enlarge too readily, replace the carbonates by the hydrates of potash or soda.

The effect of the temperature should always too be taken into account. In the height of summer the solution will work well if diluted with as much as three parts of water for lantern plates, and two parts for negative films. We find it best in practice to use with a weak solution, and should the film not enlarge to its full extent, cautiously add a little warm water.

Another point to be considered is the slight loss of density; this is immaterial in the case of lantern plates, as the development can always be carried a little further than usual, but should a negative be below printing density to start with, intensify with bichloride of mercury, and blacken with sulphite of soda before enlarging, not ammonia. Ammonia should be scrupulously avoided in hydroquinone development, and all dishes should be cleaned with methylated spirit, to quite free them from every trace of hypo, etc., or a curl in the film will ensue.

Should the film be yellow by prolonged action of the developer, the use of a ten per cent. bath of acetate of soda preliminary to enlarging, for quite a quarter of an hour, will render the film pliable and yielding, whether developed by pyro-ammonia or hydroquinone. If in doubt as to which has been used, the bath may still be used, as it has no deleterious effect on the film. Should the slightest yellowness be left in the film, it should be cleared in the hydrochloric acid clearing bath.

The developers most suitable are pyro-ammonia, using citric acid as preservative. Hydroquinone, any formula, works well, though the carbonates are to be preferred to the hydrates in the accelerator, eikonogen and mixed developers of this class. The developers least suited are the pyro-potash and pyro-ammonia, containing sulphite of soda. This is useful to bear in mind, as they are the best developers for stripping and reversing without enlargement for mechanical processes.

To strip the film without enlarging, the plate should be soaked in water and placed in a very weak solution. When quite free, transfer to a dish of clean water, soak for a few minutes, and then change the water; each change will reduce the slight enlargement. The use of methylated spirit we cannot recommend, as it makes a brittle film, destroying its adhesiveness. The transferred film should not be more than the thickness of the glass, or, in other words, the sixteenth of an inch, greater than the original, and there should be absolutely no reduction of the image.

## Societies' Meetings.

**Aberdeenshire.**—This Association held its monthly meeting on the 26th ult., Mr. Lindsay, one of the Vice-Presidents, in the chair. The Secretary (Mr. Brodie) brought up the subject of iron printing with special reference to what is known as the ferro-prussiate or blue process, the advantages and defects of which he briefly discussed. He noted that great difficulty was experienced by amateurs in obtaining paper of as good quality say as that which is supplied direct from the dealers for the purpose of copying drawings, and he suggested that surely the retailers of the paper, which is entirely of foreign manufacture, palmed off upon the amateurs their old and deteriorated stocks. An interesting conversation on the question followed. The company afterwards adjourned to the dark-room, where Mr. Main, a member of committee, gave a practical demonstration in platinum printing, employing the hot bath process, by means of which he developed a number of prints. The demonstration was of interest chiefly as showing how rapidly prints could by this process be produced, and how artistic are the results which platinum is fitted to yield.

**Cleckheaton.**—A meeting was held on the 19th ult., Dr. Suthe-land in the chair. The subject for the Monthly Competition was "Flowers." There were eleven exhibits, and the prize was awarded to Herbert Jackson. Mr. E. Hirst then read a paper on Stereoscopic Photography. The paper was illustrated with diagrams on the black-

board, and was treated in a most able and instructive manner. Upwards of sixty stereoscopic examples were shown, and a most enjoyable evening was spent.

**East London.**—General meeting 26th ult., Mr. Pasco, President, in the chair. It was definitely settled that the Society would offer a silver medal for first prize, a bronze medal for second prize, and a certificate for third prize for the open class (amateur) in general photography at the exhibition to be held in October, particulars of which will be published in a few days. After the usual business of the evening was concluded, a set of competition prints, kindly lent by the Editor of the AMATEUR PHOTOGRAPHER, was laid before the members, the particulars of each print being read out from the AMATEUR PHOTOGRAPHER Supplement, which proved both interesting and useful.

**Hackney.**—On the 26th ult., Mr. Bruce J. Capel in the chair, work done by Messrs. Grant, Gosling, Nunn, and Roberts, and a hand-camera made by Mr. Dean were exhibited. Mr. Sodeau showed an enlarged lantern slide negative  $4\frac{1}{2}$  in. square; method employed was that of Mr. Foulkes-Winkes—Soak for five minutes in 1 oz. hydrochloric acid, 10 oz. water, 10 oz. sat. alum solution; the film will then float off glass. To enlarge, immerse in 1 oz. hydrochloric acid to 20 oz. water; then float on plain glass, support and dry. Mr. H. Smith showed Beauchamp's patent metal dark slide for hand-cameras. The Chairman then called upon Mr. Foulkes-Winkes, who showed and explained several novelties, viz., album constructed to receive unmounted prints, new changing box for plates or films, and the binocular pantoscope with chromoscope attached.

**Liverpool Camera Club.**—The usual meeting was held on 27th ult., Dr. Cecil Webb presiding. The Secretary (Mr. Tansley) exhibited and explained the working of one of Messrs. G. Houghton and Son's Shuttle hand cameras, which had been kindly sent for exhibition by the makers. The camera was greatly admired for its simplicity in working, but the price is rather above the average. Reports of the club outing to Eastham and the drive through Cheshire were read by Messrs. Hawkins and Stuart respectively. The next business was an exhibition of prints and discussion upon the merits of Messrs. Eastman's gelatino-chloride paper. After many expressions of opinion and much criticism, the following resolution was passed: "That the Club is of opinion that Messrs. Eastman's gelatino-chloride is an excellent paper, both for printing and toning purposes, and gives good results with the sulpho-cyanide bath, which the members have used more than the Eastman formula. But when using the sulpho-cyanide bath it does not strip easily from the glass when squeezed down, and even this has occurred when using the bath recommended by Messrs. Eastman." It was resolved to have a Club picnic in September, and a sub-committee was formed to arrange details.

**Liverpool.**—This very popular association has just opened its new and magnificently furnished rooms in Eberle Street, and on the

28th ult. the first meeting was held there. Mr. B. J. Sayce preside, and there was a large attendance of members. The building is illuminated with the electric light, has a telephone, a studio, and several dark-rooms, possessing every convenience for the carrying on of the art of photography. Among the new members elected on Thursday night were Philip H. Nosworthy, Archibald Douglas, Mrs. C. Morrison, and R. Lawson. Mr. B. J. Sayce gave a report of the excursion to Emral and Erbistock, which took place on the 24th ult., at which thirty-six members and friends were present. About 120 exposures were made, some of the work, which was very beautiful, being shown during the evening. Mr. P. Bebbington, of 12, Cornbrook Park Road, Chester Road, Manchester, attended and explained his novel "Trafford" camera. Mr. Paul Lange showed his new American 5 by 4 camera, and Mr. Sanders, of Mount Pleasant, exhibited his novel and ingenious opera-glass camera, capable of making twenty-four exposures, as well as being useful as a telescope. The Eastman Company's new printing-out paper, and the Paget Prize Plate Company's sample packet of plates were distributed to the members. Mr. Lange gave a practical and enjoyable demonstration of the Platinotype Company's new cold-bath process, with the use of glycerine and brush manipulation. At the close the Chairman spoke of the arduous work done by Mr. J. Woolfall in arranging the new premises, which would prove of incalculable value to the members. The membership is now 300, and is increasing every month. Mr. John H. Welch, in the absence of Mr. Illingworth, the Secretary, conducted the proceedings, which were highly enjoyed. A vote of thanks to the various gentlemen who took part in the evening's illustrations concluded the proceedings.

### SOCIETIES' FIXTURES.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by TUESDAY MORNING'S POST.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

### QUERIES.

5779. **Hare's Camera.**—Should be obliged for information how to use Hare's camera, with two side wings or flaps, named Circé.—AGXOSTIC.

5780. **Hunstanton.**—Would any of your readers tell me of any places of interest near Hunstanton and Lynn? Am going to stay at Snettisham, Norfolk. And if any dark-room is available near there? There is none given in "Ilford Manual" at Hunstanton or Lynn. Any information will be gratefully received.—TRIX.

5781. **Cresco Fylma.**—What apparatus is required for enlarging with Cresco-Fylma solution? Is it easily worked?—G. D.

5782. **Llandudno.**—Will some reader kindly give addresses of reasonable, respectable lodgings in Llandudno, Bettws-y-coed, Windermere, and Lakeside?—G. D.

5783. **Mountant.**—Would any reader of AMATEUR PHOTOGRAPHER inform me best mountant for prints? I have used starch, and when dry the corners begin to come unstuck and curl.—CANTAB.

5784. **Mounting Ilford P.O.P.**—Could any reader inform me of a simple, satisfactory way of mounting prints on Ilford P.O.P., as I have great difficulty in preventing stains or marks getting on the surface? This paper to me appears much more troublesome to mount after being accustomed to ordinary silver paper, which I could damp previous to mounting, which would cause the prints to lie quite flat, which I am told must not be done with Ilford P.O.P.—F. W. G.

5785. **Glaze on Prints.**—I wish to obtain a brilliant glaze or gloss on photographs printed on Ilford P.O.P. without the ordinary process of squeegeeing on glass plate, etc. Could anyone oblige me with a formula for making a kind of varnish that could be placed on the prints with a brush that would have the desired effect? Would the liquid sold by J. Fallowfield, entitled Tylar's Brilliantine, be satisfactory for this purpose?—F. W. J.

5786. **Opera-Glass Lenses.**—Will any reader kindly tell me whether the lenses from an opera-glass can be used for a hand-camera, and if so, how should they be arranged?—W. A. F.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## ANSWERS.

5776. **Bromide Paper Developer.**—Following is good for bromide paper:—

No. 1.			
Quinol .. ..	..	..	154 gr.
Sod. sulphite ..	..	..	437 "
Sulphurous acid..	..	..	20 minims
Distilled water ..	..	..	to make 10 oz.

No. 2.			
Sodium carbonate	..	..	1,300 gr.
Pot. hydrate ..	..	..	154 "
.. bromide ..	..	..	20 "
Distilled water ..	..	..	to make 10 oz.

Mix in equal parts, and dilute with three times the quantity of water.

Clearing Solution.			
Acetic acid ..	..	..	2½ drms.
Water ..	..	..	80 oz.

—INQUISITIVE.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S POST if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

**LIVERPUDLIAN.**—The set you name is quite satisfactory. If you purchase secondhand through our "Sale and Exchange" use the deposit system.

**L. S. SMITH.**—There is no dealer of that name now in Manchester, nor do we know of a successor. Almost any optician, Perken, Son, and Rayment, Wray, Taylor, Taylor, and Hobson, Crouch and Co., would alter mount and value lens for you.

**H. A. SALWAY.**—Depth of focus, the particular quality you require, is dependent on length of focus and aperture, and we cannot suggest any lens other than the one you have, which without stopping down would give you greater depth of focus.

**NEMO.**—The stains may be due either to not rocking the plate during development, to not washing the plate well after developing, or to using an alum bath without washing—or to imperfect fixation. We can hardly give any advice without seeing negative.

**W. T. TUCKER.**—The Post Office had no right to charge 2d. for the enclosure. Print duly received.

**H. J. FULLJAMES.**—The fault of brush marks is due

to your using too much mountant. The print would be alright if rolled. The mounted print is over-toned, slightly over-printed, and the blank white sky wants breaking up with suitable clouds. "Shoreham Church" would be much improved by cutting off the path on the right. It is slightly over-toned, otherwise good technical work.

W. HOLT.—Thanks for letter.

H. BRYANS.—(1) You used your developer too strong; 1 part Rodinal, water 80 parts, bromide 10 per cent, solution 10 drops. (2) The tone is very good, but both show grey fog from too strong developer. (3) We have not forgotten your print, but have been unable to get a decent result from it.

NEVELLE.—(1) Intensify with mercury, bichloride, and ammonia. (2) In developing your plates use the pyro and ammonia, full strength, with a little extra bromide if you are certain of correct exposure; if not, develop slowly, adding the ammonia by degrees. Stick to your half-plate for general all-round work and touring; it is certainly the most convenient size.

J. N. E.—The bath should be alkaline; add 30 gr. of bicarbonate of soda to the gold solution, and then add to the bath; if acid, then add some more soda.

H. G. HAMMOND SPENCER.—Thanks for your letter. Shall hope to see some good work on your return.

HENDON.—Letter received; will answer by post.

TRIX.—(1) The only way to get over the difficulty is to shade the landscape when printed dark enough, and allow sky to go on printing. (2) The P. S. G. B. Exhibition is held in the Gallery of the Society of Water-Colourists, 5, Pall Mall East. It is usually considered the best of the year. We will answer your letter by post.

MRS. M. M. POLLARD.—No criticism has yet appeared. If you will send prints up we will send you a detailed criticism of them all, as the Special Number will not be issued for some time.

A. JANE.—(1) We could not allow you to enter our competitions under the conditions you name. (2) We cannot answer this question, because we have not made comparative tests. (3) If your chief work is portraiture stick to the portrait lens, and if necessary obtain a cheap R.R. (4) The plates named are excellent, and we like them very much indeed. (5) Your idea is not new, and there is no danger of hurting the film as long as the velvet does not press too heavily on it.

CANTAB.—We answer query next week.

H. S. JEVONS.—You would find some useful hints as to work at Portmadoc in the AMATEUR PHOTOGRAPHER "Annual." T. Jenkins, Medical Hall, has dark-room.

F. C. LAMBERT.—The precipitate is probably a mixture of iron and platinum.

A. CAMPBELL.—Many thanks for note, which goes in.

ENQUIRER.—Keep the paper you have on walls now; there is no need to alter it, and it will reflect the light about the room.

MANFIELD.—(1) The boughs of trees on left hand side are offensive, and we should like to have seen a little more rushes in the foreground, and the focussing is not quite sharp; it also strikes us that the camera was not straight. (2) Under-printed and over-toned, and the lines of the bridge are not pleasing; a good picture could be made of this spot without the boat and occupant, and with some urchins fishings. (3) One-half of this print seems to have shifted in the frame, and consequently there are doubled outlines, otherwise good, though half an inch might be spared from foreground. (4) Bad, utterly without interest, and the trees on right and left of print do not add to its beauty. We shall be very glad at any time to help you.

W. BICKFORD.—We can hardly judge from the print you send what is the matter; will you please send up a negative? We should think you are under-exposing, fogging the plates in the developer, and over-printing. Let us also know what developer you use.

BLANCH.—Letter by post.

MISS L. RIDLEY.—Is Adams' Lightning tripod, p. viii., the one you mean?

A. DALTON.—We are afraid nothing can be done for your broken negative, but will write to our man about it.

## Sale and Exchange.

ADVERTISEMENTS can be inserted under a number, the name and address being registered, and letters forwarded for a fee of 3d. to cover postage.

PAYMENTS should be made in Postal Orders or Postage Stamps.

REPORTING.—Apparatus may be sent to the EDITOR, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C., who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

Background.—For sale, background, interior, new, very cheap.—James, 10, Mount Street, Camberwell Gate.

Cameras, etc.—Lancaster's quarter-plate Le Merueilleux, with chemicals, complete, bargain, 22s.—

Mapleston, 95, Lordship Road, Stoke Newington, London, N.

5 by 4 Gutz patent camera, every possible movement, newest condition, a perfect instrument, three double backs with carriers, and complete set of film carriers, £4, cost £7 15s.—No. 320, office of this paper, 1, Creed Lane, E.C.

Whole-plate long extension Middlemiss camera, with three backs, in separate locked case, good condition, £5 10s.—Apply, S. N., 55, Vespan Road, W.

Dark Slides, etc.—Dark slides: six half good Instantographs, 6s. 6d. each; sent for approval.—Adams, Harold Wood, Essex.

Hand-camera, etc.—Houghton's Automatic, in good condition and excellent working order, rapid rectilinear lens, Thornton-Pickard shutter, carries 12 quarter-plates, instrument has done good work, price £5.—J. B. Hartness, 2, Royal Promenade, Clifton, Bristol.

No. 2 Kodak, cost £7, in perfect condition, complete with leather case and 30 exposures, will take £5 cash.—Parker, chemist, Scarborough.

Lancaster's superior Omnigraph hand-camera, leather covered, best lens, iris diaphragms, and shutter, new this season, cost price, 31s. 6d., take 21s. 6d.—Hartley, Macaulay Road, Clapham, S. W.

For sale, half-plate hand-camera, Swift's lens, Wollaston shutter, and roll-holder, covered morocco leather, like new, £10.—Further particulars from F. Bradley, Crescent House, Ilkley.

Griffiths' hand-camera, with three double dark slides and finder, in good condition, new last Christmas, price 15s., or what offers in exchange?—J. G. Harrison, 84, New Park Street, Darlington, Durham.

No. 1 Kodak, equal to new, eighty unexposed films, complete with leather case, will take £3, cost £5.—No. 318, office of this paper, 1, Creed Lane, London, E.C.

Dozen quarter-plate hand-camera sheaths, 4s.; hand-camera, quarter-plate, cost £3 15s., sell 40s.—Clarence Jones, Blackburn.

Kodak, No. 3, junior, quite new, with film, for 58 exposures, only used once, bargain £6 10s.—Hardcastle, Stonegate, York.

Hand-camera for twelve quarter-plates, three finders, one showing picture full size, rectilinear lens, covered with best morocco, equal to new, £3 5s.—Rev. J. Chapple, Lincoln.

Lenses, etc.—Half-plate rectilinear, iris diaphragms, Black Band, 18s.; 7 by 5 R.R., movable hood, Waterhouse stops, finest quality, 21s.—L., 8, Kenilworth Road, Willesden Lane, London.

Double half-plates by Laverne, 22s.; Dubroni, 20s.; single iris diaphragm Lancaster, 15s.; quarter-plate Ross, 25s.; Jamies cabinet portrait, par excellence, 39s.; approval; Ross Stereoscopic camera, six backs, leather case, 25s.—Lyne, London Road, Croydon.

Lancaster 10 by 8 rackwork landscape lens, instantaneous shutter, revolving diaphragm, complete, nearly new, price £1 5s.—Nelson, Main Street, Egremont.

Sets.—Half-plate outfit, with sundries, no reasonable offer refused.—10, Brighton Road, Stoke Newington, London, N.

Half-plate Instanto set, good as new, cost 84s., bargain, 67s. 6d.—Merrett, Russell Street, Stroud.

Half-plate camera by Morley (Light Model). Three double dark slides. With stand and case complete, £4 4s.—No. 319, office of this paper, 1, Creed Lane, E.C.

Bargain, Watson's 7½ by 5 Tourist camera, three slides, Eastman roller to fit, moveable partition for stereos and other accessories, leather case, price £5, cost more than double; also Casket, three R.R. lenses, making nine different foci from 5½ in. upwards, price £4, cost £7; on view, 54, Lime Street, City (Goy's).—No. 321, office of this paper, 1, Creed Lane, London, E.C.

Sundries.—A gentleman taking a caravan tour would like two others to join him.—F. Moore, Hagley, Hereford.

Portable studio for sale, 18 by 10 by 18, in eight sections, £10.—Photo, 134, High Street, Kingsland.

Shutter.—Thornton-Pickard time and instantaneous shutter, new condition, about 1½ hood, 16s. 6d.—Ashby, Eglwysbach, Denbighshire.

## WANTED.

Hand Camera. Wanted, hand-camera, 5 by 4, or quarter-plate, Eclipse pattern preferred.—Atkinson, Clonlec, Larnie.

Lantern.—Wanted, good triple or binial lantern, cheap, or first-class exchange.—James, 25, Brunswick Square, Camberwell.

Lenses, etc.—Wanted, battery quarter-plate lenses, half-plate kit, or Aplus Universal camera; exchange good tricycle.—Wiseman, Painswick, Glos.

Sets.—Wanted, first-class quarter-plate outfit complete, state maker's names and lowest price for cash.—"Alpha," care of Mr. Simpson, Bazaar, Windermere.

Shutter.—Wanted, Sargeant's shutter about 2 in. hood.—Ashby, Eglwysbach, Denbighshire.

Bargains in Lenses.—Ross 10 by 8 wide-angle rectilinear, rotating, fine definition, with flap shutter, £3 10s.; 8 by 5 wide-angle lens, fitted rotating stops, f/16, rapid rectilinear, best condition, take 27s.; Ross' whole-plate rapid symmetrical, Waterhouse stops, works f/8, £4 12s. 6d.; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite

new, take 65s.; 8 by 5 Ross' actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; whole-plate Suter No. 3, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; half-plate Dallmeyer rapid rectilinear, quite new, iris stops, movable hood, £4 17s. 6d.; cabinet portrait lens by Cox, rack focussing, Waterhouse stops, finest order, take 25s.; Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d.; Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; half-plate Lancaster's Instantograph lens, iris stops and instantaneous shutter, as new, 15s.; Lancaster's half-plate wide-angle lens, rotating stops, take 10s. 6d.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

Cameras! Cameras! Cameras! Lenses! Lenses! Lenses! and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, Corner Leadenhall Street, City (late Goy's Medium).

Bargains in Hand Cameras.—Adams Ideal hand-camera, carries twelve quarter-plates, finest rapid rectilinear lens, two finders, etc., as new, £5 17s. 6d.; Stienheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Luzo hand-camera, by Robinson, Regent Street, carries 100 films, rapid rectilinear, finder, as new, in leather case, take 40s.; Optimus detective camera, by Perken, Son, and Rayment, Optimus rapid (rectilinear) lens, carries six ¼-plates, covered black leather, take £4 4s.; half-plate Rover, by Lancaster, quite new Iris stops, all same shutter finder, leather case, take £3 17s. 6d.; Optimus magazine hand-camera, carries twenty-three quarter-plates, fitted Ruysscope rapid rectilinear lens, instantaneous roller blind shutter, two finders, as new, take £5 15s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 17s. 6d.; and another, 15s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, 32s. 6d.; All above warranted in very finest order.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

Bargains in Cameras and Sets.—Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide, changing box, for 24 plates, also changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; half-plate 1891 Instanto graph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; half-plate Duchess camera, all latest movements, etc., Optimus rapid rectilinear lens, fine definition, Thornton-Pickard shutter (time and instantaneous), two double slides, three-fold stand and case, as new £7 5s.; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; quarter-plate special patent, brass bound, conical leather bellows, fitted four single slides, really good lens, folding stand and case, lowest 37s. 6d.; quarter-plate Underwood's instanto, finest order, changing box for 12 ¼-plates, good lens, rotating stops, one slide, folding-stand and case, 35s.; 1891 Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.

GOOD OPPORTUNITY FOR AN AMATEUR desirous of commencing Business; capital required, £400. Business in large provincial town, returns £400; handsome shop and studio; all apparatus and requirements; carried on by a lady at present; good reason for disposal.—Apply, Reflex, office of this paper, 1, Creed Lane, E. C.

## OUR VIEWS.

"To hold as 'twere the mirror up to nature."—*Shakespeare.*

The Monday Afternoon "At Home" is discontinued for the present, but will be resumed on Monday the 5th of September.

PUBLISHING DEPARTMENT.—All letters containing Subscriptions, Orders, Remittances, SALE and EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZEL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition, No. 39.—  
 "SEA PIECES OR RIVER SCENERY." Latest day, August 22nd.—  
 Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, September 16th.)

Mr. P. S. Cox, of the Vicarage, Lynmouth, informs us that he has found among the heather on the hill at Lynmouth "An Amateur Photographer's Ready Reckoner," by Vix, containing a good many carefully-compiled notes of photographic exposures round Lynmouth and Ilfracombe. There is no name or address in the book, but the owner may have the same forwarded, on sending stamps to Mr. Cox to cover postage.

A PRINTER'S error in our note on the announcement of the opening of a dark-room at Llandudno has caused some little confusion. The notice stated that the rooms were open from 9 a.m. to 10 a.m., and our correspondent, the Hon. Secretary of the Llandudno Camera Club, writes us: "Already your notice has been of some service, as this morning (Saturday), our rooms were 'stormed' between 9 a.m. and 10 a.m., and it was only on our attendant assuring the amateur knights of the lens that the rooms would be open for thirteen hours instead of one hour that anything like order was restored." Our readers will therefore please note that the dark-room at Llandudno is open from 9 a.m. to 10 p.m.

Mr. J. Clarke, chemist, of 81, Parliament Street, Ramsey, Isle of Man, has fitted up a dark-room for the convenience of visitors, and keeps a full stock of plates, chemicals, etc.

In a book of the size of our 1892 "Annual" it would be a marvel if there were not a few typographical errors, which by some unfortunate circumstance slipped through. Our readers are requested, therefore, to make the following alterations:—On p. 221: "Jonathan Fallowfield, 146, Charing Cross Road, six doors from Oxford Street." On p. cxxii.: "Crouch's Special hand-camera lenses (largest working aperture,  $f/11$ );" obviously this should read, "Largest working aperture,  $f/5$ ," an enormous difference, which it is only fair we should call attention to.

Jonathan Fallowfield, as is well known, after thirty-four years' sojourn in Lambeth, settled down at his present address, six doors from Oxford Street, in the hopes of getting more room for his ever-increasing stock and business, but he informed us some little time ago that even now his premises were not large enough.

MAJOR H. W. B. BRUNO, the author of the articles on "A Universal Hand-Camera," informs us that Mr. Park has had a large number of applications, including foreign orders, for sets of brass work for this camera, and Mr. Park is now ready to supply complete sets made from drawings supplied by Major Bruno.

THE illustration on p. 72 of our issue of 29th ult. was, unfortunately, through pressure on our space, inserted without any reference. The negative was taken by Alfred Ironside, of Sutton, age fifteen, who had never taken a photograph before, and was fortunate enough to gain the second prize of one guinea in the Photomnibus Competition, instituted by Mr. A. R. Womald. The following are the chief rules of the second competition:—

(1) All negatives must have been taken with the "Photomnibus" camera; any plate and any developer may be used. (2) No retouching allowed. (3) Prints may be by any process, and any number, not exceeding three, may be sent in by each competitor. (4) Prints must not be mounted, but must be attached to a piece of card by passing the four corners through four diagonal slits cut in the card for the purpose. (5) All prints must be sent in to Womald and Co., Sutton, Surrey, before Monday, 31st October, together with the entrance form (see other side), duly filled up.

As most of our readers know, the Photomnibus is practically a pinhole camera; and those who wish to try this particular branch of photography, which in artistic hands leads to exceptionally fine results, should try this little apparatus.

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER or any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

## Letters to the Editor.

### A TRIP TO CHICAGO.

SIR,—I intend visiting the Chicago Exhibition, but shall certainly leave my photo gear at home if, as I understand, a duty is levied on it irrespective of its being used for ordinary amateur work. What is the use of the American clubs asking us to join them in photographic work, unless we receive a distinct denial of the impression which now so generally obtains that a heavy duty is charged by the Customs the other side. Perhaps you will insert this, so that something authoritative and certain may be forthcoming from those who have been across, and who know.

—Yours truly,

CHARLES J. HARRIS.

### THE BLISTER FRIEND.

SIR,—When I received your paper last Thursday morning, I was pleased to find the letter signed "The Baron," giving a cure for these unwelcome visitors. The reason I was pleased was that I had just taken some prints out of the washer and found several affected rather badly with that complaint, and I thought it might be the cause of my being able to save them.

I took the greatest care to follow his directions, except that I left the prints under two 56 lb. weights from Thursday one o'clock to Saturday five o'clock p.m. I removed the weights with a glad heart, thinking that I had at last found a cure for blisters, but they were, if anything, larger than when I took them out of the washer.

I write hoping you will insert this, and that it may meet the eye of "The Baron," and if he would say whether I used too much pressure, too long under the weights, or whether some important detail was omitted in his letter. Thanking you in anticipation, I remain yours truly,

UNSUCCESSFUL.

### ONE GOOD USE FOR SPOILT PLATES.

SIR,—When a dry plate is considered hopelessly fogged or worthless for use in the camera, place it under a negative and print in a frame in sunlight. When the image equals the density of a correctly exposed platinotype, develop and fix in the usual way, and the result will be a good reversed negative. Though exposed to daylight for half an hour before being placed in the frame, it will show no veil or fog.

It is convenient to cut the plate in two about half an inch from either end, so that the smaller snip of glass may be occasionally removed and the depth of printing ascertained.

The discovery is Dr. Jumeaux's, whose simple solution developer (eikonogen) is a very useful one.

S. E. VENN.

## Catalogues.

PHOTOGRAPHIC LENSES. Taylor, Taylor and Hobson, 6, Southampton Street, High Holborn, and Slate Street Works, Leicester.

This is something more than a mere price list; it contains very useful articles on "The Principles of a Lens's Action," and "How to Preserve Lenses;" besides these each series of lens is illustrated and brief instructive notes added, explaining the special purposes for which the lenses are constructed.

The special novelty now included is a new form of detective lens which has been introduced to meet the demand for a cheap lens, but it is needless to say that is also of excellent workmanship. The new lens has a focus of 5'1 in., with a working aperture of  $f/8$ , and is fitted with wheel diaphragms. We are very glad to see that this firm lay special stress upon the adoption of standard screw fittings, and set the example themselves in adopting the same, not only for flanges but also for adaptors, and actually make standard lens caps. To the man of many lenses, the possibility of fitting three or four lenses to one front is a great convenience, and the adoption of the standard screw fittings is a step in the right direction.

Since the issuing of the last price list, Messrs. Taylor, Taylor, and Hobson, have found it necessary to make extensive alterations and additions to their works, for they confine their attention not entirely to lenses, but make also levels, finders, and focussing magnifiers, and are sole agents for the well-known Blair cameras.

J. H. BALDOCK AND CO., 3, High Street, S. Norwood, S.E.

A well compiled and illustrated price list, containing all the requisite materials and apparatus for photographic workers' use. A dark-room is also offered for use of customers.

**Amateur Photographic Association.**—His Highness the Duke of Teck in the chair, a Council meeting to award the prizes was held on 27th ult. The following members were elected:—The Viscount Maitland, Mrs. E. G. Wrigley, Messrs. T. K. Mellor, E. F. Scougal, M.D., A. H. D. Steel, Craigie, E. Kennard, W. Jerome Harrison, and Miss E. A. Sykes. Mr. Melhuish, the Hon. Secretary, then laid before the meeting the pictures for the current year, which had been arranged and classified by Mr. Glaisher. There are 152 pictures in Class I., being more first-class pictures than had been contributed in any previous year. They are as follows: C. Stephens, 6; Lord de Ros, 2; R. Murray, 9; F. E. Currey, 2; W. S. Hobson, 18; Major Board, 1; General Sladen, 1; R. O. Milne, 18; R. Leventhorpe, 12; M. de Dechy, 6; W. Gaddum, 3; J. C. Cohen, 6; Colonel Foster, 3; F. G. Smart, 7; The Vicomte de Condeixa, 9; H. O. Hutchinson, 5; F. Wrigley, 2; Miss Mahon, 3; A. R. Dresser, 9; H. Emmons, 3; E. F. Scougal, M.D., 1; The Viscount Maitland, 8; and W. Jerome Harrison, 18. The rest of the pictures were comprised in Classes 2, 3, and 4. The following prizes were awarded:—First prize, to the Vicomte de Condeixa, a large silver goblet; R. O. Milne, a silver goblet; C. Stephens, an album, handsomely bound; M. de Dechy, a large silver medal; A. R. Dresser, an album, handsomely bound; The Viscount Maitland, a medal; W. S. Hobson, a silver goblet; R. Leventhorpe, a picture in frame; W. J. Harrison, a large silver medal; F. G. Smart, an album, handsomely bound; Colonel Foster, a picture in frame; J. C. Cohen, a medal; H. O. Hutchinson, an album, handsomely bound; W. Gaddum, a medal; H. Emmons, a medal; R. Murray, a medal. A vote of thanks was passed to Mr. Glaisher for the time and care he had bestowed on the arrangement and classification of the pictures. The pictures are now on view at the offices of the Society, 58, Pall Mall (opposite Marlborough House).

## Photographic Procedure.

By E. J. WALL,

Author of the "Dictionary of Photography."

### SECTION VI.

#### DEVELOPERS AND DEVELOPMENT.

(Continued from page 76.)

In treating the subject of this section it would be better possibly for some of my readers if each developer in general use be considered in turn. The developers now used may be briefly stated, as ferrous oxalate, pyrogallol, hydroquinone, eikonogen, and paramidophenol.

But before treating of one particular developer we may say that there are one or two statements which apply to all the agents. In each developer there are: (1) the developing agent proper; (2) the restrainer, the action of which is practically to prevent the formation of fog; (3) the accelerator, which hastens the action of the developing agent.

*Ferrous Oxalate Developer.*—This developer is considerably less used now than it was even two or three years ago; its greatest adherents were the Continental workers, but with the introduction of hydroquinone even they have abandoned its use in favour of the latter agent, to a great extent.

The main features of the ferrous oxalate developer are that it has not much tendency to reduce the haloid salt of silver which has not been affected by light, and also that the colour of the image, a blue black, presents less obstacle to the passage of light than the brown image of pyro-developed negatives, and it is therefore necessary to carry development a great deal further than when using pyro.

It is a generally accepted axiom that there is far less control over the action of the ferrous-oxalate developer than with other agents, that, in fact, it is not easy to compensate for errors in exposure by altering the proportions of the constituents of the developer. This is to a great extent true, although in intelligent hands ferrous oxalate may be modified to suit particular cases. It will be noted that I have here practically disregarded Messrs. Hurter and Driffeld's researches, which they state have proved that it is impossible to correct or alter the results obtained by exposure. This I have done on purpose, for a reason which we shall come to later on when talking of pyro development.

We have already given the formulæ for the ferrous oxalate developer (pages 464) but for convenience sake they are again included here.

##### I. ONE-SOLUTION DEVELOPER.

Ferrous oxalate (dry) ... ..	1 oz.
Neutral oxalate of potash ... ..	4 "
Distilled water ... ..	12 ozs.

Allow to stand for at least twelve hours, shaking occasionally, then decant from the undissolved ferrous oxalate.

##### II. TWO-SOLUTION DEVELOPER.

###### Solution A.

Neutral oxalate of potash ... ..	1 part
Distilled water ... ..	4 parts
Sulphuric acid, <i>q. s.</i>	

###### Solution B.

Ferrous sulphate ... ..	1 part
Distilled water ... ..	4 parts
Sulphuric acid, <i>q. s.</i>	

If we take the ordinary method of making ferrous oxalate—that is the second formula, in two solutions—there are one or two points to consider in the actual making and keeping

of the developer. The oxalate solution is easy to make and easy to keep. If distilled water at about 70 deg. to 80 deg. F. be used, the salt will dissolve without much trouble, with occasional shaking. The solution should be slightly acid, which may be effected by adding a few crystals of oxalic acid, a little powdered tartaric or citric acid, though these two latter act slightly as restrainers, or sulphuric acid may be used. The solution will keep indefinitely if a well corked or stoppered bottle be used. If ordinary tap water be used for making this solution, a white chalky precipitate (oxalate of lime) is formed, which settles to the bottom of the bottle, and may be filtered out, or the solution decanted from it.

The solution of sulphate of iron or ferrous sulphate requires a little more care in preparation. The iron salt should be in bright emerald green crystals, without any adherent brown powder on their surfaces; if the latter be present it is advisable to allow a little extra salt, about 10 or 20 gr. to every ounce, and, placing the crystals on a piece of thin muslin stretched over the mouth of a tumbler or graduate, wash them once or twice by pouring a little water over them. Distilled water should be used always for making the iron solution, or else it very rapidly becomes oxidised and useless. It is always a somewhat difficult matter to keep the iron solution, and many have been the expedients suggested, such as pouring oil or paraffin on the top of the solution, and drawing the supply from the bottom of the solution. The best method of keeping it is undoubtedly to pour it whilst still warm into 1 oz. phials, to fill the same quite full, and then cork; by this means there will practically be no enclosed oxygen, and so small a quantity as one ounce will be soon used up. The iron solution should always be acidulated, preferably with sulphuric acid, one or two drops to the ounce being sufficient.

The usual proportion of the two solutions is one part of iron solution to four parts of oxalate; stronger than this it is not advisable to use, or else a yellow sandy deposit of ferrous oxalate is precipitated, this deposition also taking place if the oxalate is weak. When this developer is mixed it is also essential that the iron should be added to the oxalate, and not *vice versa*, for the same reason.

For a correctly exposed plate this developer may be used without any further addition, and the image will appear in from ten to thirty seconds, and development be completed in about three or four minutes, though, of course, these times are only approximate and differ with the character of the emulsion. With some plates an addition of a restrainer, such as bromide of potassium, is advisable, and from ten to twenty drops of a ten per cent solution of this salt may be added to every ounce of mixed developer. It is a very good method of working to apply the developer to the plate, and rock the dish and allow development to proceed till the whole or nearly the whole of the image is visible, and then to measure out the requisite quantity of bromide solution and pour the developer from the dish into the graduate, and then pour back on to the plate, and allow development to proceed. When bromide is used, the negatives are a little richer in contrast, take rather longer to develop, and the shadows clearer. In no case should development be stopped till the details in the shadows are well visible, and it may safely be said that in most cases the surface of the plate should be almost entirely black, and the image lost to view, except by holding it up to the light.

An alternative and tentative method of development may be used, and in this case it is advisable to commence development with the full quantity of oxalate solution, but to add only one-fourth or one-sixth of the iron, and then add the remainder as development proceeds.

## DEVELOPING UNDER-EXPOSED PLATES.

The best method of developing much under-exposed plates or snap-shots is to soak them first of all in a very weak solution of hyposulphite of soda 1 part, water 3,000 parts, or 1 gr. of hyposulphite in 7 oz. of distilled water, for one minute, and then to drain the plate slightly and apply the ordinary ferrous oxalate developer with 1 gr. of bromide to every ounce. The image appears very quickly, but development has to be rather prolonged to gain sufficient density.

When from its behaviour in the ordinary developer it is found that a plate has been slightly under-exposed, hyposulphite may be added to the developer in the proportion of three drops of a 1 in 200 solution to every ounce of developer.

It is almost superfluous to add that with a strongly under-exposed plate it is almost impossible even by these means to obtain sufficient detail, and possibly, or at least I think, there is less chance of saving under-exposed plates with ferrous oxalate developer than with pyro or other agents.

## DEVELOPING OVER-EXPOSED PLATES.

As with pyro development, the best method of saving over-exposed plates is to soak them first of all in a solution of bromide of potassium about 2 gr. to the ounce of water, and then without rinsing to apply a developer weak in iron composed of the normal quantity of oxalate and one-half the quantity of iron—that is, one part of iron to eight parts of oxalate. Or if with great over-exposure, it is advisable to use old developer first.

With regard to the old, once-used developer, it is as well not to throw this away, but keep it in a separate bottle, as it may not only be utilised as a very powerful restrainer, but even for ordinary work it is useful, as will be seen later, and it may also be used for bromide paper and lantern slides, and a very good reducer may be made from it.

## DEVELOPING PLATES THE EXPOSURE OF WHICH IS UNKNOWN.

It often happens that we are in doubt as to whether we have correctly exposed our plates, and it is advisable then to hasten slowly. In such cases the old, once-used developer comes in very handy. If this be applied to the plate, and the image appears normally, we may continue development as long as the details appear and the image gains in density. Should, however, the detail or density hang fire, then one-third or half the quantity of fresh developer may be added. In such a case as this the one-solution oxalate developer comes in useful and serves to strengthen the old developer.

(To be continued.)

**Warrington.**—The usual monthly meeting was held on the 5th inst., a large number of members being present. In the absence of the President, Mr. T. J. Down, Mr. H. N. Houghton presided. A practical demonstration on the working of the Ilford printing-out paper was given by Mr. J. H. Brown Penketh, commencing first by giving its history, the manufacture, the advantages over other silver papers, rules to be observed, printing, toning, fixing, defects, and remedies, etc. Prints were passed round showing the various colours obtained through injudicious handling, such as stained fingers, dirty dishes, etc. Two prints were next washed, toned, and dried on glass with successful results. Mr. Lawson, of Newton-le-Willows, another member, introduced to the meeting his Patent Limelight Saturator, as shown before the London Lantern Society. Judging from the ingenious make and its simple action, it bids well for success, especially to those lanternists who are in the habit of exhibiting in country places where hydrogen gas cannot be obtained, the saturator doing away with the gas altogether. Mr. Lawson is making a new one on the same lines, that can be made to fit into any lantern. After the usual vote of thanks to the essayists, an enjoyable and interesting meeting was brought to a close. Mr. W. H. Gyton was elected a member of the society.

## General and Photographic Chemistry.

By E. C. CONRAD, F.C.S.

## II.—GENERAL LAWS AND TERMS.

(Continued from page 86.)

**Organic and Inorganic Chemistry.**—Chemistry embraces such a large number of substances that it is advantageous to divide them into separate classes. The term organic chemistry has been applied to those compounds which contain carbon (with a few exceptions), and includes all those substances that exist ready formed in animal and vegetable organisms, as well as a far larger number which are manufactured by chemical processes. Those substances that do not contain carbon, and most of which may be said to have a mineral origin, are classed as inorganic compounds and studied under that branch of chemistry.

These divisions are quite arbitrary, there being no difference in the laws governing the two classes.

**Metals and Non-metals.**—The elements themselves are also arbitrarily divided into two classes, called metals and non-metals. The first class, containing those that have a bright lustre, are good conductors of heat and electricity, and are of high specific gravity. They are all, with the exception of mercury, solids, at ordinary temperatures, and they all combine with oxygen and sulphur. The second class contains the gases and such solids as carbon and sulphur.

There are 48 metals and 15 non-metals, reckoning arsenic, in the second class.

**Oxides and Sulphides.**—The union of the elements with oxygen produces a class of bodies called oxides, and their union with sulphur produces a class called sulphides.

**Anhydrides.**—Some oxides, on being dissolved in water, produce acid liquids; these when dry are called anhydrides. This term is also used to express anything in a completely dry state absolutely free from water.

**Carbonates.**—Oxygen and carbon unite together to form an acid radical ( $\text{CO}_2$ ) called carbon dioxide in an anhydrous condition, and in solution carbonic acid, and this radical combines with many oxides to form a series of salts called carbonates, e.g., sodium carbonate,  $\text{Na}_2\text{O}, \text{CO}_2$  or  $\text{Na}_2\text{CO}_3$ .

**Acids and Bases.**—Those bodies which turn vegetable blue solutions, red, and decompose carbonates, and contain hydrogen capable of being replaced, are termed acids. Any metal that replaces hydrogen in an acid is called a base.

**Salts.**—The compound produced by the union of a base with an acid is called a salt. Common salt can be taken as a type of these compounds; it is a union of the metal sodium with the chlorine of hydrochloric acid,  $\text{Na} + \text{HCl} = \text{NaCl} + \text{H}$ .

**Nomenclature of Acids and Salts.**—Although all acids must contain replaceable hydrogen, yet they are usually named from the amount of oxygen contained in the acid radical, expressed by a terminal or prefix; the normal acid being distinguished by the termination *ic*, the one immediately below it in amount of oxygen ending in *ous*, while the ones above or below this have the prefixes *per* (over or above), and *hypo* (under or lower). The salts are always formed by changing the *ic* into *ate* and the *ous* into *ite*.

A list of the acids containing chlorine and the resulting sodium salts will explain this.

Hypochlorous acid	$\text{HClO}$	Sodium hypochlorite
Chlorous	" $\text{HClO}_2$	" chlorite
Chloric	" $\text{HClO}_3$	" chlorate
Perchloric	" $\text{HClO}_4$	" perchlorate

The acids that are composed of hydrogen and another element all end in *ic*, and the salts take the termination *ide*.

Hydrochloric acid, HCl; sodium chloride, NaCl; silver chloride AgCl.

**Empirical Formulae.**—If we have the total percentage of all the elements in a compound, its formula can be calculated in the following way. An analysis of sulphuric acid gives the following percentage:

		A.	B.
2.04	per cent of hydrogen	2.04	2
32.65	" " sulphur	1.02	1
65.31	" " oxygen	4.08	4

100.00

Now if the percentage of each element is divided by its atomic weight (viz., the  $\frac{2.04}{1}$ , the  $\frac{32.65}{32}$ , and the  $\frac{65.31}{16}$ ), the

figures in column A are obtained, and the lowest of those (in this instance the sulphur) is divided into itself and all the others (to the nearest whole number), the results in column B are obtained, viz., 2 of hydrogen, 1 of sulphur, and 4 of oxygen, or  $H_2SO_4$ , which is the experimental or empirical formula of sulphuric acid. When the formula of a compound is known, its percentage composition can be calculated by multiplying the total combining weight of each element by 100, and dividing this by the combining weight of the compound. Calculate the percentage of oxygen in sulphuric acid thus,  $\frac{4 \times 16 \times 100}{98}$ .

**Allotropy and Isomerism.**—Many of the elements are found to exist under different conditions, which often show a wide divergence in physical properties and chemical activity. Thus sulphur and phosphorus can be obtained in several modifications, which will be discussed under their respective heads. It is usual to call the less important or latest discovered varieties of an element its *allotropic* form, or *allotrope*.

There are also a large number of compounds which exhibit the same peculiarity. Thus there are two pent-oxides of antimony,  $Sb_2O_5$ , having the same empirical formula but different chemical and physical properties. They are said to be *isomers* one of the other; most instances occur among the carbon compounds.

**Temperature and Pressure.**—Both temperature and pressure affect chemical action and also the volume or mass, and therefore the weight of all substances. Unless otherwise stated, all experiments are supposed to be conducted at the standard temperature and pressure, which are taken as  $0^\circ C. = 32^\circ F.$  for temperature, and 760 millimetres = 29.92 inches of mercury for pressure.

The temperature is measured by a thermometer, which is, roughly speaking, a narrow tube closed at both ends, free from air, and containing some substance that expands and contracts equally for all alterations of temperature. They are usually made of glass, and filled with mercury or alcohol, and graduated into degrees, or tenths or fifths of degrees.

There are three scales in general use, namely, the Centigrade, Fahrenheit, and Reaumur. The Centigrade takes its unit from the temperature of frozen water, and its maximum from boiling water, and divides the interval into 100 divisions or degrees. The Reaumur takes the same maximum and minimum, but divides the interval into 80 degrees. The Fahrenheit takes its maximum from boiling water the same as the others, but its minimum from the temperature of a freezing mixture of snow and salt, and divides the interval into 212 degrees. The relation of the degrees on the Fahrenheit to those on the Centigrade is as 9 to 5, between Centigrade and Reaumur as 5 to 4, and the formula for converting Fahrenheit into Centigrade is

$$C = \frac{5(F - 32)}{9} \text{ of Centigrade into Fahrenheit } F = \frac{9C}{5} + 32.$$

The Centigrade scale is the most rational, and the one usually adopted for scientific purposes. In practice it is a matter of indifference which is used, provided it is an accurate instrument.

The pressure is measured by a barometer, which is usually a glass tube closed at one end, and about 33 inches long, filled with mercury, and inverted into a cup also containing mercury, or sometimes with the open end curved up. The height of the mercury in the tube will vary with the pressure of the air on the open end.

Gases are more particularly affected by alterations of temperature and pressure. All gases expand for an increase, or contract for a decrease of temperature (the pressure being equal)  $\frac{1}{273}$  of their volume for every degree Centigrade. Thus 273 volumes of a gas at  $0^\circ C.$  will be 274 volumes at  $1^\circ C.$  The volume of a gas (the temperature being the same) varies inversely as the pressure; that is, the volume increases for a decrease of pressure, and decreases for an increase of pressure.

**Specific Gravity.**—The specific weight of a substance is its weight in comparison with the weight of a similar bulk of another substance. Water is the substance usually employed, and substances are quoted as being lighter or heavier than water, expressed by a number called its specific gravity. Thus water = 1,000, ether = .720, sulphuric acid = 1.842 at  $15^\circ C.$ , the usual temperature for taking specific gravities.

To obtain the specific gravity with accuracy a chemical balance must be used, and care in manipulation, and attention to many details, are required.

For ordinary purposes a hydrometer will be sufficiently accurate.

For further particulars of the above, and other branches of chemical physics, the larger manuals must be consulted.

**Entry Forms** for the "Holidays with the Camera" and "Annual Lantern Slide" Competitions are now ready, and will be forwarded on application.

## How to Make a Set of Photo-graphic Apparatus.

By H. J.

### CHAPTER II.

#### A DOUBLE-EXTENSION CAMERA.

THE camera which forms the subject of this paper will be found a far superior article to the one described in the first chapter, including as it does every possible movement that is of any practical use, both of front and back. It can also be used with lenses from four inches to nineteen inches

FIG. 10.

focus, without the baseboard cutting off any portion of the view, the back being made to move forward when using short-focus lenses. Of course, the fittings for a camera of this description will be more costly than the other one; but it is folly to "spoil the ship for a pennyworth of tar," so in the following list I have included everything that is needed for a first-class camera. As to procuring the fittings, I can only say the same as in the last (and the same thing applies to the whole of the series of papers),—I will get them at these prices if my readers cannot do so. The following is the list of what is required for a half-plate camera:—

	s.	d.
Racks and pinion for focussing .. ..	5	3
Extension rods and nuts (to fix front in position) ..	1	6
Guide strips for extending front, and strips to form grooves in reversing back for dark slide ..	2	3
Side hinges and stays, with screws complete ..	5	6
Reversing back clips and clip hinges .. ..	1	4
Focussing screen hinges, stops, and turn-button ..	1	6
Slotted plate and screw for rising front ..	1	0
Screw and nut for baseboard .. ..	0	8
Screws to fix above .. ..	1	0
Brass strip for front standards, stops, etc. ..	1	0
<b>Total .. ..</b>	<b>21</b>	<b>0</b>
Leather bellows (varnished) .. ..	6	6
Cloth .. ..	4	6

A patent turntable can also be supplied at 10s. 6d., which includes royalty, if anyone prefers it to the ordinary tripod head.

The baseboard is the first part to make. This will require to be  $8\frac{1}{2}$  inches square, and as it is rather complicated at first sight, I must request you to give particular attention to my instructions, and also examine the drawings carefully,

when you will find all difficulties disappear. In the first place prepare a piece 18 inches long, of the section as shown in fig. 15; the size is 1 inch by  $\frac{3}{4}$  inch. Now cut in two equal lengths, and then prepare a piece  $7\frac{1}{2}$  inches long by  $8\frac{1}{2}$  inches wide; this being smaller in length than width looks curious; but by the *length* I mean the way the grain of the wood runs, and the reason for it having to be this way is, that when it is screwed into the rabbets in the former pieces the grain of one runs opposite to that of the other, and thus adds to the strength. See fig. 11, which is a plan of bottom of baseboard; and fig. 12, which is a section of same on line A B. The middle piece must, before screwing to the side pieces, have two trenches cut along its width, that is *across*

the grain, one inch from each edge, and the right width and depth for the rack to slide in easily; this can be tried by the racks themselves, also one other trench crossing these two, one inch from one side; this one must be deep and wide enough for the pinion to lie in easily. See fig. 19, which shows plan of top of main part of baseboard; and fig. 20, which shows section on line E F. These three trenches having been cut, let in the bridge bearing of pinion (fig. 16) into the board, so as it is level with the top, and so that the pinion itself when laid in its trench with the end inserted in the bearing will project about a sixteenth of an inch above the bottom of the other trenches, so as to engage with the teeth of racks (see fig. 20).

The middle board can now be screwed and glued into the large rabbet of the side pieces, keeping the screws even and straight so as to look neat, and the extending part can be proceeded with. The grain of this must run crossways again, the same as the other; therefore we require a piece  $6\frac{3}{4}$  inches long and  $8\frac{1}{2}$  inches wide. It had better be prepared 9 inches wide, so as to leave a little to clean off; rabbet this on each edge so

FIG. 11.

that it will slide easily, but without any side play, in the grooves formed in side pieces of baseboard. Then make another rabbet along each edge  $\frac{3}{8}$  inch on and  $\frac{1}{4}$  inch deep; see fig. 13 and fig. 17, B. These rabbets are to form grooves for the feet of extension rods, of which I will say more further on. Now run the sliding extension into the baseboard in its place and mark at each end the proper position of racks, underneath of course; and before taking out, plane the ends to the proper size, and then take it out and screw on racks and slide in again to make sure they are in the

right place, and will work easily and without friction. Then take it out once more and bore a hole for pinion through the side piece. Be sure and make the hole large enough to allow a little play to and fro, as it is a great chance if it comes exact the first time; and the plate bearing will keep it right. This bearing must now be let into the side, keeping it at the right distance from end of baseboard, so that the pinion is square across, and also so that it projects the same height in each trench, so as to catch the teeth of both racks; it can be screwed on temporarily

FIG. 12.

and tried before letting in so as to make certain of its being quite correct. If you intend having a turn-table in the baseboard, now is the time to fix it; this can be done with a fret-saw, but to those who possess a lathe, the best way would be to fix the baseboard on face plate and turn the hole out; but for those who have neither lathe nor fret-saw, the way will be to mark it round and bore a series of holes with the centre-bit, touching one another, and finishing with gouge and spokeshave. This way will do very well, as the brass rim of turn-table will cover any slight irregularity,

FIG. 13.

though the hole should be cut as true as possible, as it is a very bad plan to do bad work and trust to its being covered up. The baseboard should now be put together; that is, the sliding part put in, and both ends be cleaned off, so that it measures exactly  $8\frac{1}{2}$  inches, and a small brass stop let in under the sliding part, so as to catch the front of main part and prevent the pinion from turning it back beyond level, or it would prevent the camera from closing properly.

The front of camera, or rather the frame for the front to slide up and down in, can now be made. For this purpose

FIG. 14.

prepare two pieces 7 inches long and  $\frac{5}{8}$  inch square; these must have a hole down the middle lengthways, as shown in fig. 21, which is a section through the front frame, close to the bottom.

These holes are for the extension rods, and as it is an awkward job to bore them quite true by hand, and it is very unlikely that my readers will be able to do it by machinery, we must find some other way to do it. The best way will be to make the pieces larger, say about  $1\frac{1}{4}$  inches square, and bore the holes (which must be  $\frac{1}{4}$  inch in diameter) before planing up, then by measuring  $\frac{5}{16}$  inch from

the centre of holes each way at each end, and continuing the marks along the sides, the pieces can be reduced to the proper size ( $\frac{5}{8}$  inch square), with the hole perfectly in the centre. An eighth of an inch groove must then be run down one side of each of these pieces (which it must be understood are the uprights of the front frame) leaving an eighth on one side and three-eighths on the other side of groove; see fig. 21. Now prepare the bottom piece of front frame; this will be  $1\frac{1}{4}$  inches by 1 inch, and about 7 inches long.

FIG. 15.

FIG. 16.

FIG. 17.

When you have prepared this you have to get the exact length between the uprights; to do this, place the feet of extension rods in the grooves made for them in sliding part of baseboard B, figs. 13, 14, and 17 (C, fig. 14, shows the feet in their respective grooves, the round spot representing the rod); now on each rod slide one upright with the grooves facing each other, then measure carefully the exact distance between; now take the bottom piece and cut out at each end a recess so that the uprights will just fit in it and come level with the front, taking care to leave a small tongue on it to fit in each groove, and cutting it the same length from one recess to the other, as the two uprights were apart when in their places. The bottom piece will now be the same shape as the light part of fig. 21. The back edge D can now be bevelled into the uprights so as to show as at D, fig. 10. The three pieces can now be fixed together by screwing through this bevelled part into the uprights, and also by putting a screw through each upright into the bottom piece as shown, taking care

FIG. 19.

that neither screw penetrates into the hole for extension rod. I omitted to say that the uprights should be cut to the right length, 7 inches, before putting together, as it is easier to get them both the same length then than it would after. The top of the frame is held

together by a strip of brass screwed on the front of the uprights, as will be seen in the figure of front in the next chapter. The front itself can now be made and fitted; this is formed of a piece of  $\frac{1}{4}$  inch mahogany rabbeted to

FIG. 20.

slide up and down in the grooves of uprights; as the back of it will only come level with the back of grooves, it will only be necessary to rabbet it on the front, and it should be level with front of uprights, and a small bead should be run up the joint where it comes to the uprights; as it gives it a better finish. The front should be just square, that is as high as it is wide, and will want a hole in the middle for lens, which can now be made, if you have got the

lens, but if not leave it till you have, so that it can be made the right size at once, as it will be found more trouble to alter it than it was to make it at first, especially if it is made too large. The camera body is the next part to proceed with, but as I promised in my first paper to describe the way to dovetail it together, I must postpone it for another chapter, in which I shall also show how to fix the brass work and finish the camera. There will be plenty to do in the above until next week, when the same will be continued.

FIG. 21.

 U. Brass top piece to front frame.  
 V. Rising front.  
 W. Slotted plate for ditto.

(To be continued.)

## Apparatus.

## HANNAM'S MOUNTS.

HANNAM AND COMPANY, of 25, Soho Square, W., and Atlas Works, Gainsborough, have forwarded us a large parcel of photographic mounts of all sorts and sizes, which are of first-class quality and reasonable in price.

One special line which strikes us as exceptionally useful to our readers are the boxes and packets of assorted mounts. Those of our readers who use more than one size camera, or are brave enough to trim their prints well, will find these assorted lots of great service. The mounts are of the same quality as sold by the hundred or dozen, and may be obtained either with or without margins. Besides this it gives the worker a chance of picking and choosing and fitting his mount to his paper, as the packets include Oxford lines, the well-known Gainsborough, Atlas, Princess, and other varieties manufactured by this firm.

Messrs. Hannam are also making a special line of cheap Oxford mounts, which we have tested chemically and find to be quite free from "bleach" or any deleterious chemical. For exhibitors some very fine mounts, to hold six or four prints, according to size, are made; and the most striking and artistic mount is the "Whatman," which is a rough-surface mount, with gold bevelled edges and plate-sunk mark, and are specially suitable for platinum or bromide prints.

It will be impossible for us to mention every variety of mount sent us, but the London show-rooms are situate at 25, Soho Square, which is very easy of access, and a catalogue, which contains many requisites besides the mounts, will be sent on application.

## THE DEVELOPAN.

The Developan Manufacturing Company, of 130, Charing Cross Road, London, W.C., have introduced a novelty, which consists of a light papier-maché tray and cover. The tray is provided with a pane of deep ruby glass and the lid with a light orange one, thus the whole forms a transparent box which may be used in an ordinary room by day or artificial light. To insert the plate in the Developan it would only be necessary to place both dark slide and the apparatus in a changing bag, or under an opaque cloth. An aperture at the top is provided, into which the developer may be poured in and out.

This little contrivance will be very useful both on tour and to enable an amateur to show in comfort the operation of developing to his friends.

## ADAMS' CLUB ALBUM.

Adams and Co., of Aldersgate Street and 26, Charing Cross Road, have sent us a very neat little album, which they have christened "The Club."

It is provided with stout cardboard leaves with apertures cut in it for quarter-plate prints, two on each page, the print being slipped under the front of the cardboard. This entirely obviates the trouble of mounting or trimming prints, which are so often unsuccessfully performed by amateurs, especially with the gelatino-chloride papers.

The album is made in two sizes to hold 96 and 192 quarter-plate prints, and the prices are 5s. and 10s. each respectively. For hand-camera workers and those using quarter-plate cameras in the usual way, this album will be a great boon, and we hope that Messrs. Adams will introduce albums of similar construction in larger sizes, as the advantages of being able to dispense with mounting and to change the prints as desired will be of great convenience.

For postal clubs also the album should be very useful, and as it is handsomely bound in leather with gilt edges, it will form an ornament to any table.

**The American League of Amateur Photographers.**—Thirty-six delegates representing twenty-one amateur photographers' clubs in various parts of the United States met at the rooms of the Society of Amateur Photographers of New York, 113, West Thirty-eighth Street, and approved of the plan and adopted a constitution and the name of the American League of Amateur Photographers. The league is patterned in many respects after the league of American Wheelmen. It is established to bring about a closer union between camera societies, to promote the science and art of photography, to encourage and advance photography separate from its trade, commercial, or professional relations, and to bring members into closer relationship in acquiring useful information. A division will be organised in each State, and a national council will be held in May 1893, to consist of three delegates and three alternates from each club. State divisions will appoint local officers in each town or centre, who will secure privileges and advantages, and furnish information to a member on presentation of his membership card. Arrangements will be made with hotels to furnish dark-rooms and other conveniences for photographers. The league will publish a journal, and the new organisation will take the place of the American Photographic Conference. It is proposed to secure to members a special discount in purchasing photographic materials. The membership dues will be one dollar yearly, and can be forwarded to the general secretary, T. J. Burton, 113, W. Thirty-eighth Street, New York. Officers of the National Council were elected on July 21st as follows: President—Paul L. V. Thiery, Newark (N. J.) Camera Club; First Vice-President—Dr. George L. Parmele, Camera Club of Hartford, Conn.; Second Vice-President—Frances B. Johnson, Washington (D. C.) Camera Club; Treasurer—W. H. Drew, Lynn (Mass.) Camera Club; Secretary—T. J. Burton, Society of Amateur Photographers of New York. The New York division of the league was organised at the Amateur Society's rooms, and these officers were elected: President—Frank La Manna, Brooklyn Academy of Photography; First Vice-President—Dr. Ely Van Der Walker, Syracuse Camera Club; Second Vice-President—James H. Stebbins, Jr., New York Society of Amateur Photographers; Secretary, Treasurer—H. S. Fowler, Brooklyn Academy of Photography.—*New York Times*.

## A Holiday in Norway.

PHOTOGRAPHY AMONG THE FJORDS.

(Concluded from page 53.)

### IV.—THE HARDANGER FJORD.

AFTER Bergen there was only one more fjord for us to visit, the incomparable Hardanger, gemmed with wooded islands that lay freshly fair in its smooth waters, and running a hundred miles inland through some of the most beautiful scenery in Norway. Not wildly grand and darkly majestic, like those we had visited further north, were the hills of the Hardanger, but broken by happy valleys, where the cattle quietly grazed in fields of fertile green. These lent variety and the charm of contrast to the snow-clad peaks and the slumbering hills, and the human element introduced by the many hamlets nestling in the hollows heightened the romance of the scene. Thus there was an indescribable exhilaration in the journey from Bergen to Odde, first through the outer fringe of islands that protect the country from the sea and then through the sunny fjord itself. Amongst the verdant islands, through the silver-shining reaches where the land receded, under the wooded cliffs where the waters narrowed,

mountain source that it cuts the fjord almost in two, and in rough weather, as on the occasion of our visit, its course may be traced right to the opposite bank. It was necessary to cross this turbulent stream, but it was not till after two futile attempts that we succeeded, and ran into a quiet little cove on the other side. There began a mountain path, to traverse which a clear head and plenty of nerve and muscle are necessary. Rising through a grove of fragrant pine trees, under whose dark tresses, mingled with the dainty plumage of the silver birch and the sober, smooth-stemmed ash, gleamed the wildly flowing waters of the Tyssa below us on our right, the way led into a steep and rocky gorge, up which we climbed by seemingly impossible paths. Ever in our ears sounded the roar of the rushing rapids beneath, at first loud and sullen, but as we climbed becoming fainter, till they were scarce heard above the sighing of the wind-kissed trees. Now up a natural stair of jagged stones, now along a trelliswork of tangled roots, here across a slanting rock, where a single tree laid across the smooth and slippery surface gave a sure foothold; sliding, slipping, scrambling, leaping, for nearly 2,000 feet up the precipitous sides of the gorge, we followed our nimble guide. From this highest point the road descended slightly as the hills curved round to the right, and at last took us off the rocks on to the turf again in the little mountain valley, where the

MILL ON THE SANDVENDAL-ODDE.

past the Mauranger, whence one may sleigh across the famous Folgefond glacier to Odde, on and on we went till the northernmost point at Utne was rounded, and we turned south into the Sør Fjord, and ran down its narrow length to our destination at Odde. The Sør Fjord, though in places like the Hardanger, with many pleasant villages set on its green and shelving shores, yet in general resembles more the stern and majestic beauty of the Fjerlands. Its shores are so rocky and steep in places, as, for instance, between Odde and Tyssedal, that no landing place can be found along them, and the fjord itself is the great highway of communication.

#### THROUGH THE TYSSedal.

By this highway, immediately after the dropping of the anchor, a small party set out for the grandest and most difficult excursion that can be made from Odde—to the Skjæggedalsfos, or, as it is sometimes called, the Ringedalsfos. At the outset a mishap nearly occurred, for a sudden storm sprang up while we were rowing down the fjord and almost swamped the boat. The danger was rendered all the greater by the violence with which the Tyssa, a mountain stream starting from the fall, pours its troubled waters into the fjord. So impetuously does it rush from its

Skjæggedals Hotel is built. This hotel is unique. The only mode of access to it is that which we had made use of down the four miles of fjord from Odde and over the seven miles of climbing inland from the mouth of the Tyssa. Yet the accommodation is excellent, and the dinner earned by the passage of the Tyssedal is sure to be a good one.

#### THE RINGEDALSVAND AND THE SKJÆGGEDALSFOS.

From the hotel the journey to the fall was resumed by boat, first over a still, deep lake whose clear waters revealed the rocks the rowers skilfully steered us through. This lake we found to be really only a stage in the progress of the Skjæggedalsfos from its mountain home to its rest in the fjord. We had climbed up the torrent which formed the last stage, and reached the lake, which now in its turn led us to another lake, the grand and gloomy Ringedalsvand. Down a magnificent terrace of falls considerably more than a hundred yards wide, broken in places by mighty boulders, around and over which the white foam wildly leapt, the Ringedalsvand plunged into the lesser lake, which, in its turn, fell into the Tyssa. But, fine as this fall was, we dared not stay. Five miles still lay between us and the Skjæggedalsfos, five miles of hard rowing over the

Ringedalsvand, which lay dark and cold and still beneath the encircling cliffs. There was something very weird and awesome about this great silent lake 1,500 feet above the level of the fjord below, and as our little boat, though urged on by four stalwart pairs of arms, crept slowly and laboriously from point to point, in spite of the grandeur of the hills and the beauty of the falls, a feeling of oppression and of gloom stole insensibly upon us. The gaunt, grey mountains all around us, rising in castled pinnacles and rocky turrets far into that still air and cutting off the half of heaven from our view, the eternal snows far up the heights, the sighing murmur of the ever-falling streams, the ceaseless shimmer of the ice-cold waters of the lake, the scant and stunted trees, the scars and seams wrought in the mountains' sides by the downward rush of falls that long had ceased to be—these things impressed us with a sense of melancholy and of sadness. And then, after passing the twin falls of the Tyssestrængene, the floating ice in the lake and the hollow thunder of falling water prepared us for the Skjæggedalsfos. From dizzy heights that no man has ever scaled, into a gloomy chasm cloven out of the blue glacier ice, wreathed and folded in flying mists of spray, boiling, foaming, roaring, and leaping, the majestic volume of water thundered in

made the way seem all too short. Then at last at our feet lay the fjord which we had left so tossed and driven by the wind, serene and still in the faintly flushing light of dawn, and barred from shore to shore with great bands of silver light over which we rowed till we came to the ship again.

#### FAREWELL TO NORWAY.

From Odde there are other excursions to the beautiful Lotefos and Espelandsfos, to the famous Buarbræ, approached somewhat after the fashion of the Skjæggedals, and to the Folgefond Glacier, across which a sleigh-drive can be taken. It was on the Wednesday morning that we left Odde, retraced our way through the Sør Fjord, ran on to Ulvik and into the pretty Graven Fjord, with Eide set like a jewel at its far end, and then turned our faces homeward. But it was long before we got clear of Norway, for all down the beautiful Hardanger lay our course, while the long day through,

"High on his unpartitioned throne  
The heaven's hot tyrant sat alone,  
And like the fabled king of old  
Was turning all he touched to gold."

It was evening ere we left the last of the encircling islands astern, and then, when the shore was lost to sight behind us, still

ODDE AND THE SØR FJORD.

its might, the grandest cataract in Europe. But it was difficult to pay any lengthy homage to this royal fall, for the blinding spray chilled us through, and the glacier slope on which we stood afforded no very safe footing, and broke off abruptly to plunge into the cavern below. Therefore we soon descended to the lake by the slippery path up which we had climbed. In the wet grass between the foot of the fall and the water's edge grew one little spray of forget-me-not, which was at once seized and borne off as a trophy. As we returned over the lake, the Folgefond Glacier lay full in front of us, and its broad white bosom caught the dying rose of sunset, and, though many miles away, threw a dull flame-coloured light upon the sullen waters of the Ringedalsvand that accorded well with the gloomy grandeur of the scene. By the time the hotel was reached, the dusk of twilight had deepened, so that the return journey over that rough mountain track began to look formidable. Yet, after a rest, we struck up among the sharp and jagged stones into the hills again. It is an oft-disputed question whether it is better to ascend or to descend a hill. The journey down through the Tyssedal settled that question for us—it is better to ascend. But the glory of the dawn as it fell on the pale faces of those great grey rocks, and warmed them with its glowing touch, and chased the dusk of the brief night down through the long ravine,

the snowy foreheads of the hills rose golden with the sun's last ray. Thus we bade farewell to Norway, ringed round with mountains and encircled by the sea, and sped on our way southwards into the darkening night. A quick passage brought us to Newcastle, whose noisy clamour fell strangely on ears accustomed to the eternal silence of the fjords, and then we scattered up and down the length and breadth of the land, and our holiday in Norway became a memory only.

One or two little duties have to be discharged. Every passenger on board the *City of Richmond* owed much of his enjoyment to Captain Bentzon, whose perfect skill had taken the ship in safety over a journey of 2,020 miles, and whose charming courtesy endeared him to all with whom he came in contact. The *fiasco* at the start, thanks to the energy with which Mr. and Mrs. Rimmer faced the situation, was forgotten before the first day closed; and for this Mr. Fennell, of Liverpool, who at a moment's notice undertook the catering arrangements, deserved the acknowledgment he received. On the whole the first cruise of the *City of Richmond* to the land of the fjords must be pronounced a conspicuous success. For those who have no knowledge of Norway it is far better to make acquaintance with the country and the people in this way first, and afterwards to go unhampered to the place or places which make upon them the best impression.

**ADAMS & CO.'S 1892 ANNUAL NOW READY.**

published. Produced at a cost of Two SHILLINGS per copy.

**PRICE SIXPENCE.**

Circulates over the whole world, contains particulars of dozens of absolute novelties, and is the most complete record of photographic progress ever published. Post free, ONE SHILLING. 400 pages and 500 Illustrations.

### ADAMS & CO.'S 'ADJUSTABLE' SHUTTER.

NO FITTING REQUIRED.

A  $\frac{1}{4}$ -pl. fits any  $\frac{1}{2}$  pl. Lens; a  $\frac{1}{2}$  pl. any  $\frac{1}{4}$  pl., and so on. Extremely small and light, works at set speed from  $\frac{1}{4}$  to 1/100 of a second; also time exposure. Gives the necessary extra exposure to foreground. One of the best and simplest of Shutters, as well as cheapest.

$\frac{1}{4}$ pl. complete	...	17/-
$\frac{1}{2}$ pl. "	...	21/-
1/1 pl. "	...	25/-

### THE 'IDEAL' HAND CAMERA

Has received the highest awards wherever its work has been exhibited; also won the Silver Medal (highest possible award) and Six First Position.

It is the ONLY Automatic Camera that is entirely free from complications and the ONLY one that CANNOT get out of order. Every Camera is GUARANTEED.

No. 1. Fixed Focus, best Rectilinear Lens	...	£7 net.
No. 2. Made to Focus, with WRAY Lens...	...	£8 10s. net.

### THE 'ADAMS' HAND CAMERA Latest Pattern.

Ross 5 by 4 Rapid Symmetrical Lens, Shutter opening from and closing to centre in diaphragm slot, giving 80 per cent. of light. Objects focussed on a screen. Reservoirs interchangeable. Takes plates, out films, or Roll Holder. Used on stand as well as in hand. Is an all-round Camera, perfect even in small details, and is the HIGHEST CLASS and MOST EXQUISITE Camera it is possible to buy.

$\frac{1}{4}$ pl. complete, in case	...	£15 15s. net.
$\frac{5}{8}$ pl. "	...	£18 18s. "

## ADAMS &amp; CO.'S

## 'HAT'

## Detective Camera.

A perfect Detective Camera of marvellous ingenuity. Takes plates  $\frac{1}{4}$  and  $\frac{3}{4}$ . Fitted with best rectilinear lens, and shutter working in diaphragm slot. Weighs  $2\frac{1}{2}$  ozs. only, as carried.

Price, with 2 slides ... 63/- net.

This Camera is most strongly recommended. Fitting done free.

## ADAMS &amp; CO.'S

## 'VESTA'

## Pocket Camera

A Folding Hand Camera for  $4\frac{1}{4}$  by  $3\frac{1}{4}$  plates that may be carried in the pocket. Complete with Dark Slide, Lens, Shutter, Focussing Screen, and Reversible Finder. Wray Lens, Pneumatic Shutter, properly timed, and Swing Back for upright pictures. Only  $1\frac{1}{2}$  in. thick, and ONLY WEIGHS 1 lb. WITH Double Dark Slide and two Plates. Must

be seen to be believed. One of our many great photographic triumphs.

Complete, in case with 3 Double Backs ... £7 7s. net.

## Magic Lantern Matters.\*

BY W. J. CHADWICK.

ON the present occasion I shall not have much to say about the magic lantern anterior to the introduction of Marcy's Sciopticon (from America) by the late W. B. Woodbury. Of course it is quite true that we had lanterns before the sciopticon, and these were of two types, one for burning oil which was nothing more than a toy—and a poor one at that—quite unsuitable for anything more than showing painted slips on screens very little larger than a pocket handkerchief; the other was a big clumsy oxyhydrogen lantern, which was chiefly used for Sunday School meetings, mechanics' institutions and by a few private exhibitors and lecturers. We had occasionally a good deal of talk about using the lantern for educational purposes, but there was very little practical work done in this direction; not many amateur photographers made lantern slides, or paid much attention to them in those days. But there were a few commercial firms who produced lantern slides, and the introduction of the sciopticon must have vastly increased their business, for that beautiful little instrument not only filled up the gap between the already existing instruments; it did more, it was capable of taking the place of both; with its two-wick oil lamp it was possible to exhibit photographs in the drawing-room on from five to six feet and up to seven feet screens without much trouble, and also by the same instrument, using limelight, the largest screens were just as brilliantly illuminated as by the most ponderous lantern ever constructed; indeed, the sciopticon came at the right time, it was just the very thing that was wanted, and it became so popular as to be almost a part of every amateur's paraphernalia.

I believe it to be a fact that Woodbury did take provisional patent protection for the sciopticon lamp in this country, and that during the first year they were placed upon the market over 400 were supplied, but by an oversight, or we may say neglect, for Woodbury was not a business man, the patent was not completed. Other firms took advantage of this, and very soon placed similar lanterns before the public at a slightly reduced price. I am informed that one firm alone supplied over 1,000 of these in the following year. We had not long to wait before several so-called improvements were introduced and patented, but it may be said that nearly all the oil-burning lamps for lantern purposes used to-day are more or less the progeny of the sciopticon.

The sciopticon was originally constructed to burn two one and a half inch wicks, placed edgewise to the condenser, and with the exception of some improvements in the combustion chamber, made by Mr. George Smith, the present proprietor and manufacturer, it remains in its original state. Some of the so-called improved lamps are made to use three, four, and as many as five

wicks, and these up to two inches and two and a half inches wide, either placed parallel, converging, or diverging, and some again take other forms, the intention being to increase the illuminating power.

Now, if it were necessary, I could give my experiences of many years with nearly all these multiple wick-lamps, and down to the latest patent before the public; but, to be brief, I see no advantage in them for the purpose for which oil lamps are suitable. There undoubtedly is in some an increase in the size of flame; but for lantern purposes a large volume of flame is not required. It is intensity that is necessary, and the intensity must be in the right place, which is the focus of the condenser, and is confined to a very small area, and it can be shown to be a positive disadvantage to have more volume than is required.

Then, again, the enormous heat given off by some of these powerful lamps, resembling a roaring furnace, is another very great disadvantage. Added to this is the difficulty to keep the wicks burning evenly, by reason of unequal combustion, for very soon the wicks begin to "fork," one flame gets higher or lower than the rest, the thing begins to smoke, to smell, the light goes bad, and the whole affair has to be re-adjusted; but with the two-wick lamp there are none of these troubles. It is quite easy to adjust the lamp at the commencement, as not to require the slightest attention for three or four hours.

It has been stated by some amateur lanternists that with So-and-So's or somebody else's lamp they have exhibited ten feet pictures, and we know there are some gentlemen who are always cleverer than everybody else, and sometimes these gentlemen are so carried away by their enthusiasm as to believe they have done something big, or, at any rate, to tell us so. I can light my dining-room by a farthing candle, but I do not think you would care to be entertained at dinner by such illumination. Then, we have somebody's lamp compared to limelight. Well, of course, we can compare the light of a candle to the electric arc light; but for *equality* of illumination the comparison is a very poor one.

The limit in size of a picture shown by any oil lamp is, in my opinion, six feet square where photographs are the

subjects, but it is possible to select a few photographs of certain subjects that might be tolerated to seven feet, and perhaps more, but after seven or eight feet the blow-through limelight becomes necessary, and this may be used up to ten or even twelve feet, and after that the mixed jet, with oxygen and hydrogen under pressure, is indispensable. Ether may be used in place of hydrogen or coal gas, but I see no advantage in its use in any way.

The oil-lamp, then, as I have stated, is only suitable up to six-foot screens, and the question comes now, is six feet large enough? The answer to that is, it depends where it is to be used and the size of the audience. I have given a good deal of pleasure to private friends at home by even a less picture, but in a private drawing-room or a dining-room it is not always convenient to fix a six-foot screen, and very often when it is con-

THE DOM KIRKE, BERGEN. [A Holiday in Norway]

\* Read before the South Manchester Photographic Society.

venient there is either a fire burning in the room or some abominable reflections, that cause a good deal of trouble by interfering considerably with the results. All these objections are dispensed with by using a transparent screen such as I now introduce. In this little waterproof case, not unlike an umbrella cover, except that it is a little longer, is a roll of a particular kind of semi-transparent paper three feet eight inches wide. The outer end of it is attached by six drawing pins to a wooden lath five-eighths of an inch square, having suitable fittings for attaching to two light stands, also contained in the waterproof case. The screen, as you will see, can be erected on one end of a dining-room table in three minutes; and, if the table is long enough, the lantern can be placed at the other end. The audience sit in front, and I think you will be surprised to see how beautiful pictures look when projected in this way. The reflections from the house fire do not interfere with the results in the slightest degree. We may even permit a tolerable light in the room, and you may strike a match to light your cigar without seriously impairing the brilliancy of the picture. And, now that all is ready, you see a beautifully illuminated picture three feet six inches square by a sciopticon, and which I maintain is large enough for most private house exhibitions, or even in a small schoolroom, where the audience is not too large.

I am not advocating small screens in preference to large ones, for all depends upon circumstances; but I do prefer a well-lighted small screen to a large one with inferior illumination, and especially so when we can get to the best position from which to view the pictures; and here another matter may be of interest.

The lanternist inquires what is the most suitable size screen for a certain size room? and the audience ask which are the best seats to see the picture from? To say that the screen ought to be in proportion to the size of the room is the general way of putting it, and to sit about the middle of the room is the usual reply to the best position.

Now, it is an established fact, which was recently demonstrated at the Stereoscopic Club, that the most correct position from which to view any photograph is at the angle at which the photograph was taken. Thus, if we make a picture by a twelve-inch lens, and we wish to appreciate size and perspective correctly, we must view the picture at twelve inches from the eye. To examine it at a nearer distance is equal to it being taken by a longer focus lens than twelve inches; and to see it at a greater distance gives the impressions of one taken by a shorter focus lens. Then, if we make quarter-plate negatives by a five-inch lens, to see it correctly we must either use a magnifying glass or a stereoscope, or we may magnify it by the lantern; but the principle is just the same. If we make lantern slides by contact from quarter-plate negatives taken by five-inch lenses, and mask these down to  $2\frac{3}{4}$  inches, as is usual, and then project these slides to 6 feet, we have a magnification of 26 diameters; then 26 by 5 (focus of lens) gives 11 feet. If we project the slide to 12 feet,

or about 52 diameters, this, multiplied by 5, will show us that, at 22 feet, we should see the pictures at their best; and, from what has now been said, it will be understood how incorrect it is to make lantern slides which are to be shown in series from negatives taken by lenses of different foci, or what comes to the same thing, is making contact slides from quarter-plate negatives and other contact slides from portions of whole-plate and even larger negatives.

At a lantern exhibition, not very long ago, a series of slides of Haddon Hall were shown. The photographer had used a nine-inch focus lens for most of the exterior views, but for all the interiors a five-inch lens was used. I well remember the view from the terrace steps, showing the main front of the building, with the ball room windows; and the next view was the interior

of the ball-room. It looked so very large, that no person in the world who did not know the architecture could have imagined a room of such dimensions to be contained in the building we had just seen upon the screen. It was as ridiculous as for an architect to submit unfigured plans of the rooms in a house all drawn to different scales, to fill up the paper, and where the bath-room and the w.c. might be shown the same size as the dining-room, no true idea could be formed from such drawings or such photographs.

A similar misuse in lenses was made by a friend of mine who went to Norway last year; he had a half-plate camera, and a seven-inch rapid rectilinear lens. About half the number of his pictures were taken by this lens, and the others by one of the combinations of the lens only, which would be about fourteen inches focus. He said it saved him the trouble of walking or climbing to places where, say, a waterfall would have been too small to fill his plate if taken by the seven-inch combination; the result is, that nearly all the waterfalls in Norway, judging from his pictures, are the same size, and no true appreciation of size or distance is possible from his series of pictures.

About the artistic side of the question, I am not here to-night to discuss, though admitting there may be circumstances where, on the

same size plate, a seven-inch lens will be better than a five-inch, or *vice versa*, but I repeat, and with emphasis, that the too frequent use of lenses of great disparity in focus for lantern slides is a mistake.

It may be said in conclusion that the focus of the lantern objective has nothing whatever to do with the subject of this communication.

A NORWEGIAN BRIDE. [A Holiday in Norway.]

**Hackney**—On 2nd inst. the seventy-third meeting was held, Mr. W. P. Dando presiding. Members' work was shown by Messrs. Capel, Nunn, and Reynolds. Mr. Dando showed a series of views taken whilst with the Convention. Question asked. Why does the P. O. P. print sometimes purple and sometimes red, and which gives the best toning? Reply: When fresh it gives the purple tint; with absorption of damp the paper prints the red tone, which is preferable, as it tones to a richer shade.

## Societies' Meetings.

**Bath.**—An excursion took place on 29th ult., to Castle Combe and district. The party, including several ladies, left this city by brake at 11.30 a.m., and proceeding through Box, Corsham, and Pickwick reached Castle Combe about two o'clock. Here they were received by Dr. Sudlow, who refreshed his visitors and drove with them to Grittleton House, some two miles distant, the seat of Sir Algernon Neeld, Bart. The house is of very beautiful proportions and design, with richly ornamental grounds. Having viewed these outside attractions and photographed them, the doctor, armed with the necessary permission, conducted the society through the two spacious picture galleries, filled with very valuable paintings and statuary. Returning again to Castle Combe, and, after a brief rest, the doctor piloted the society through Mr. Lowndes' beautiful park, where more photographs of the Manor House and adjacent attractions were obtained. At seven o'clock, and somewhat tired, the party returned to the Dower House, Dr. Sudlow's residence, where tea was awaiting them, and two hours later the departure from this delightful valley was taken.

**Lewisham.**—Ordinary meeting held on 5th inst., Mr. A. H. Miles (Vice-President) in the chair. The chairman gave a very graphic description of the club outing to Rochester on July 23rd, and some proofs of work done on that day were handed round for inspection. Mr. H. L. Davis then gave a short and lucid paper on "Hand-Camera Work," in which he embodied many of the essential qualifications to be looked for in selecting a hand-camera. He exhibited and explained the working of Shew's Eclipse camera. An interesting discussion followed, during which the opinion was expressed that for general work it was best to use a stand with a hand-camera, Adams's Lightning stand being recommended.

**North Middlesex.**—On 8th inst., the President, Mr. G. W. Marchant, in the chair, 30 members were present, and four new members elected. The Secretary was called upon to open a discussion upon the various methods of obtaining harmonious prints from harsh negatives. During the evening Messrs. Pither, Cherry, Cox, Forbes, Gill, and the Chairman spoke on the subject. The method of harmonising harsh negatives by rehalogenisation and redevelopment was chiefly dealt with, and prints from negatives before and after treatment by this method were shown and a demonstration of the process was given. Prints from negatives taken at the outings to West Drayton and Boxmoor were entered for competition. The vote of merit was accorded to Mr. Wall for West Drayton, and to Mr. Cherry for Boxmoor. A vote of thanks to the Chairman concluded the business. The next meeting will be held on August 22nd, when Mr. Wall will take the chair, and Mr. Debenham will address the Society upon "Carbon Transparencies." Visitors welcome.

**Putney.**—On the 23rd ult. the members met at Molesey Bridge and proceeded to the lock and weir, where some interesting views were taken. From Molesey the river bank was followed past Hampton Court and Thames Ditton to Surbiton. The day being the occasion of the Kingston regatta there was a rare opportunity for obtaining hand-camera negatives of the river crowded with pleasure craft of all kinds and sizes, not forgetting the City state barge, the *Maria Wood*, so well known to all frequenters of the upper reaches of the river. Before proceeding on their holiday tours several members tested plates and films of various makes to compare their respective qualities, and much useful and practical information was obtained. Mr. Gorin exposed three of the new "Sandell" plates on the same subject—a clump of trees and bushes surrounding a pond; working in a fair, diffused light, at 5 p.m., with a stop of  $f/22$ , he gave one plate an exposure of about 1-20th sec., another 1 sec., and the third 20 sec. The negatives were developed with pyro and ammonia, and all three came out extremely well, the snap-shot being only slightly under-exposed, the 1 sec. correctly exposed, and the 20 sec. exposure having none of the usual signs of extreme over-exposure; in fact, with more experience in the manipulation of these plates, and particularly in judging the density when developing, there can be little doubt that the under-exposure could have been greatly modified, and that the over-exposure would have yielded a negative in no way inferior to the apparently correct exposure of 1 sec. Mr. Zachariasen carried out some experiments on the relative merits of plain and isochromatic films, the latter with and without a yellow screen. The subject chosen for the experiment contained yellow houses with red facings, pale blue blinds, blue slates, and light and heavy foliage in the fore and back ground. The results obtained fully confirmed previous experience that for some subjects the iso films have decided advantages, and that this is increased by the use of the yellow screen. The screen was of a light lemon colour, increasing the exposure four times, as proved by the following experiment:—A half-plate film was exposed in camera divided by a stereo division, one half being exposed for five seconds through a lens fitted with the yellow screen, the other half through a plain lens for  $1\frac{1}{4}$  sec.; the uncut film was then developed, the two nega-

tives appeared at the same time, and development proceeded steadily; when taken out, both were equally developed, proving the relative correctness of the two exposures. A gas lantern fitted with a 2 foot burner, and provided with a deep ruby glass 8 in. by 6 in., and a ground-glass placed inside was used during the development; this gave a soft and even illumination, quite ample for judging detail and density. Care was taken to carry on development at some 4 feet from the lantern, approaching it only to watch progress. The edges of the films kept perfectly clear; it is therefore obvious that no fogging took place, and that the objection occasionally raised to the use of isochromatic plates and films that they must be developed in a very feeble light is not a serious inconvenience when the bright light is of the right quality and carefully used. The next outing of the Society will take place at Carshalton on August 6th.

**Rochdale.**—A capital day's outing was spent by the members on the 6th inst., the place selected being Ingleton. Rochdale was left at 7 o'clock, Ingleton being reached at about 11.30. The first thought that seemed to strike the members of the party was dinner, to which ample justice was done at one of the hotels. After satisfying the inner man, work was at once commenced. After a walk through the village, the party entered this pretty district by what is known as the Storrs Entrance, including Quarry Wood, Twistleton Glen, Snow Falls, Yew Tree Gorge, Black Hole Falls, etc. The return route was by Twistleton Hall, Ravenwray, Thornton Force, Pecca Bridge, Swilla Glen, and Broadwood. After having worked most of the chief points of interest, tracks were made for tea, and after counting up, etc., it was found that 118 exposures had been made. The return journey was commenced at 8 o'clock, Rochdale being reached at a little after 11 o'clock, each member being well pleased with the day's outing, one or two of whom had rather exciting adventures. Mr. Thomas Leach had the leadership of the excursion, and its success owes a great deal to him for his excellent knowledge of the district.

**Rotherham.**—The monthly meeting took place on the 2nd inst. Dr. Baldwin (President) occupied the chair, and there was a good attendance of members. A petition against proposed restrictions on photographers at the World's Chicago Columbian Exposition was agreed to. The Hon. Secretary exhibited a series of ordinary silver prints made twenty-eight years ago by a local worker; although mounted and no special pains had been taken with regard to them, they had undergone very little (if any) change. Prints on Eastman's gelatino-chloride paper were also shown, and were very favourably criticised. It was agreed that the third excursion of the season should take place on Saturday, August 13th. The place chosen was the Rivelin Valley, near Sheffield. Mr. A. T. Cocking, mining surveyor, and one of the staff of the Firth College, Sheffield, then gave an address on photographic chemistry, confining his attention principally to changes which salts of silver undergo in printing and its after processes. His remarks were illustrated by several experiments. On the 5th inst. the Council of the society made arrangements for the annual members' competition. There will be five classes, viz.: A, six untouched negatives; B, three untouched negatives and prints therefrom (1892 excursion work); C, four negatives and prints—open only to those who have not hitherto gained an award; D, six prints; and E, six lantern slides. At an art and industrial exhibition held in connection with the Rotherham School of Science and Art, on July 28th, 29th, and 30th, and August 1st, several of the society's members sent specimens of work done. Certificates of merit were awarded to Mr. Rackstraw and Mr. Hemmingway.

**South London.**—Ordinary meeting on 4th inst., the President, Mr. F. W. Edwards, in the chair. The evening was devoted to the explanation and demonstration of various printing processes. Mr. G. W. Moss read a paper explaining his method of preparing and coating of paper by the collodio-chloride printing-out process (which will appear next week), and showed specimens of work on paper of his own preparation. The Fry Manufacturing Company exhibited some pictures printed on their Soltype paper. The manipulation of this paper appeared to be very simple, and the tones of the finished prints were much admired by the members present. The Honorary Secretary suggested as an aid to focussing, the fixing of microscopic cover glasses to the focussing screen with Canada balsam, which enabled a focussing eye-piece to be used with great facility. It was announced that the President offered a prize for the best picture produced on the sample Paget plates, a large number of which were distributed at the meeting, the results to be judged on the 5th of September.

**Tunbridge Wells.**—The ordinary meeting was held on the 4th inst., Mr. Ernest R. Ashton in the chair. The Shuttle hand-camera attracted a good deal of attention, the plate-changing apparatus being universally commended; several members expressing an opinion that it was the best arrangement they had seen. The Hon. Secretary reported he had practically used it, and the working of the Shuttle was eminently satisfactory. The same firm sent down an album with moveable pages, which was considered a great ad-

vance on the ordinary albums, as every page was detachable, and consequently could be removed at pleasure. The vignetting table worked during the evening, and it was agreed that it fulfilled all that was claimed for it, and would perfectly vignette a large number of frames. It was thought to be a great advantage to have the opportunity of viewing these articles at the meeting. The rest of the evening was taken up with the inspection of the "Inland Scenery" prints sent in for competition to the AMATEUR PHOTOGRAPHER. This was a very large collection, and the meeting was much prolonged in consequence, as the prints were subjected to a good deal of criticism, several being much admired. Mr. Cassingham showed the new metal printing frames, and the new print trimmer. The final arrangements were completed for the excursion to Maidstone on the 9th inst.

**Directions for the Use of Rodinal.**—When exposing plates for Rodinal, a much shorter exposure is required, viz. about half that given for pyro. To develop, use 1 part of Rodinal, and 24 to 30 parts of water. The image even on under-exposed plates will appear rather rapidly, although it becomes more conspicuous only after three or four minutes, thus leaving sufficient time to watch the progress of development. (1) Under-exposed plates you can generally finish developing with a dilution of 1:30, without obtaining a negative with too great contrasts. Should there be a considerable under-exposure, add to the solution another 5 to 10 parts of water. Rodinal not being an agent to fog the image, developing may be continued for a very long time. You will then obtain a soft negative, with an image properly and harmoniously worked up which, if required, may be intensified. (2) Should the plate, on developing with a solution of 1:30, prove to be over-exposed, remove the developer from the tray and add to it, in order to make it work with greater contrasts,

an ample quantity of solution of bromide of potassium and a few drops of undiluted Rodinal. To this end it will be found useful always to hold ready a solution of 1 part of bromide of potassium cryst., 3 parts of water, 3 parts of Rodinal, to be added by drops. (3) Should, in cases of normally-timed exposures, after developing for three or four minutes, the image not be of sufficient strength, it will be due either to the plate being of a kind working particularly smoothly, or to the photograph having been taken in an especially dull light (landscapes, for instance). In either case the employment of a developer working with greater contrasts will be necessary. The same directions as for over-exposures should here be followed. (4) You should always develop somewhat beyond the desired intensity, in order that the negative, after fixing, may still be of sufficient strength. (5) Bromide paper should generally be developed with a solution of 1 part of Rodinal, 100 to 200 parts of water. Some kinds, however, require a stronger solution, viz., 1 part of Rodinal, 40 to 80 parts of water. *Fixing Bath.*—For fixing purposes the ordinary bath of hyposulphite of soda may be employed, although an acidulated bath will always work more reliably. To obtain this, dissolve 1 part of fixing salt (a new preparation lately brought out by the Actien-Gesellschaft für Anilin-Fabrikation) in 8 parts of water; or dissolve 5 parts of sulphite of sodium (cryst.) in 100 parts of water, acidulate with 1 part of concentrated sulphuric acid, and then add 20 parts of hyposulphite of soda. Rodinal will work well together with hydroquinone, making an excellent "one solution" developer. When time is an object, Rodinal can be conveniently used in connection with other developers by first developing with Rodinal, to obtain details, and then finishing the development with pyro, eikonogen, or hydroquinone to get the required density. The same density, however, can be obtained by simply continuing the development with Rodinal.

**Production of Platinum in Russia.**—The platinum beds of the Ural mountains, says the *Journal de la Chambre de Commerce de Constantinople*, are the only ones in the world in which this metal is found in grains. Platinum is found in Brazil and in the Cordilleras in the hard serpentine rocks, but never in the form of grains. The platinum beds of the Ural mountains are found in various districts. In the north, at Besserski, in the government of Perm, in the district of Khotourski, and in the State properties of Gromlagodatski, where sixty-six mining concessions have been granted. All the beds of the northern region are situated in the basin of the River Touri, in that of the tributary stream of Taghil, and in other tributaries higher up. On the western declivity of the Ural mountains there is another platinum bed near the river Outka, a tributary of the Tchoussova, and the basins of the higher tributaries of the Outka, near the Ural river. The platinum found in these places is in the form of grains, in sand frequently containing gold. The weight of these grains is from 17 to 21 grammes to every 1,640 kilogrammes of sand. The richness of the platinum beds varies in the same proportions. In some, the thickness of the turf covering the sand does not exceed from 2.16 metres to 2.88 metres, while in others it varies from 10.80 metres to 14 metres, so that it becomes necessary to work underground. The thickness of the platinum sands does not vary much. A noticeable characteristic of it is that they are found in the form of friable grit, and easily washable. The clayey sand is rarely met with. The beds in the northern districts of the Ural mountains are most frequently of little depth, thus allowing the turf to be easily removed and the platinum is quickly reached. The platinum found in this district contains a considerable proportion of gold, whereas that found in the Taghil district contains hardly any. Moreover, the Northern platinum and that of the Taghil district are very different in appearance. The former appears clear and very brilliant, while the latter is of a dull colour and is frequently found mixed with rare metals such as iridium and osmium. The size of the grains is about the same in the two beds.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns **MUST** be received by **TUESDAY MORNING'S POST**.

5. The Editor does not undertake to answer questions by post.

6. In answering Queries, correspondents are requested to mention, in every instance the *number and full title of the query* referred to.

### QUERIES.

5787. **Yarmouth and Lowestoft.**—May I again ask any kind reader to tell me of any special pretty little bits for half-plate pictures in or near Yarmouth, Lowestoft, Beccles, or neighbourhood? Any information will be most gratefully received.—*TRIX.*

*Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."*

### QUERIES UNANSWERED.

July 15th.—No. 5756.

" 22nd.—Nos. 5763, 5768.

July 29th.—Nos. 5777, 5778.

Aug. 5th.—Nos. 5779, 5780, 5781, 5785, 5786.

### ANSWERS.

5760. **Platinotype.**—No licence is required for working this process. The new cold-bath process is as simple as any other printing process, and there is no special apparatus required, merely a dish and some solution of oxalate of potash. It is entirely different to Clark's platinum toning, in which a silver print on plain paper is obtained, and the image then toned with a solution of chloroplatinite of potash. In the platinotype process the platinum is on the paper in conjunction with an iron salt, the latter being reduced by light and the reduction product in turn reducing the platinum salt to the metallic state.—*THE EDITOR.*

5760. **Platinotype.**—With the platinotype paper you also purchase an implied license to use the same. The new process lately brought out by the Platinotype Company is exceedingly simple and the cost is very little more than the silver printing. There are

no points of similarity between the ordinary platino-type printing and Lyonel Clark's toning process.—THE SMITH.

5761. **Seplatype**.—There is a paper of this name issued by Sharp and Hitchmough, of Liverpool, which gives very warm brown prints. It is printed out like silver paper, and then after soaking is fixed in a dilute solution of hypo. Most of the commercial photographs of this colour are, however, produced by the carbon process.—THE SMITH.

5761. **Seplatype**.—This is a special printing process. Messrs Sharp and Hitchmough, 101, Dale Street, Liverpool, are the agents, and will give you all information. It is a patent and secret process.—THE EDITOR.

5762. **Hand-Camera**.—5½ in. is the best focus for a hand-camera lens.—EDITOR.

5762. **Hand-Camera**.—The most useful focal length for all-round work is 5 to 5½ in. A rapid lens of shorter focus will not cover a quarter-plate so well, and if a longer focus be used, then the depth of focus suffers, unless a small stop be employed.—THE SMITH.

5764. **Sulpho-Cyanide Toning Bath, Ilford Formula**.—Probably some decomposition has taken place, and the bath has become acid. Provided the bath is kept alkaline it will keep at least a month. You do not state whether there is any deposit in the bath, or whether the one print toned was well washed first, and therefore one has to answer somewhat in the dark.—THE EDITOR.

5765. **Ferrotypes**.—Jonathan Fallowfield, 146, Charing Cross Road, sells some dry ferrotype plates with which it is possible to finish a photograph in a few seconds. Full instructions are sent out with each box of plates. There are no glass plates in the market which are specially prepared for this purpose.—THE EDITOR.

5766. **Sat. Sol. Hypo**.—The strength of a saturated solution of hypo or any other salt depends entirely on the temperature of the solution, and therefore, this not being given, it is impossible to give a definite answer. It is far preferable to make a solution of definite strength and dilute down as required. If you weigh out a pound of hypo and put into a saucepan with 16 oz. of water, and heat till dissolved, you can easily measure the quantity of the resulting solution when cool, and add sufficient water to make of some definite strength, such as 1 in 3, or 1 in 4.—THE EDITOR.

5766. **Sat. Sol. Hypo**.—At 59 deg. F. 1 oz. of solution contains 1 oz. hypo (Janeway).—THE SMITH.

5767. **Distant Photography**.—Fix the telescope in front of the lens, either with a brass adaptor to screw on to the lens mount, or by a sleeve of light-tight material. The size of the image depends upon the extent to which the camera is extended, and the focussing is effected by adjusting the distance between the eye-piece and the objective of telescope. The field of a telescope is, as a rule, limited to a very narrow angle, and is also very curved; therefore very successful results cannot be expected. The exposure would probably be very short, and is best estimated by judging the image on the screen.—THE EDITOR.

5769. **Studio Builders**.—Davenport and Co., 32, Parkhouse Street, Camberwell, E.C.; Overend and Co., West Green, Tottenham, London, N.; Houghton and Sons, 49, High Holborn, London, W.C.—THE EDITOR.

5772. **Powell's Compressed Gold Baths**.—A good black tone does not depend much upon the toning bath, but upon the quality of the negative. A good, bold, plucky negative printing under green glass and a strong toning bath may sometimes do it. Try—

Phosphate of soda . . . . . 1 drin.

Sulphocyanide of ammonia . . . . . 1 "

Distilled water . . . . . 8 oz.

Dissolve and add—

Chloride of gold . . . . . 4 gr.

Carbonate of soda . . . . . 20 "

Black tones are the most difficult of all to obtain. The fact that your prints turn red in the fixing bath shows you do not carry toning far enough.—THE EDITOR.

5773. **Hand-Camera Shutter**.—Amongst so many shutters it is a difficult task to choose one, but the Thornton-Pickard safety snap-shot shutter is efficient and cheap.—THE EDITOR.

5773. **Hand-Camera Shutter**.—I doubt if you can find one more suitable than the Thornton-Pickard snap-shot shutter with safety blind. The price is about 10s.—THE SMITH.

5774. **Snap Shot**.—Provided the lens covers the plate, your first surmise might be correct, as light leakage would cause fog, not lack of density. If your shutter works outside the lens and is one of the "go and return" variety, that might be responsible for the faulty illumination. Let the sky of your picture fall on that side of your plate, and you will be able to get natural clouds in your negative.—THE SMITH.

5774. **Snap Shot**.—The want of density may be due to the shutter acting as a diaphragm and cutting off some of the light, or to the material of the dark-slide hinge acting on the film, and thus causing loss of density. If you will send a negative or two up, we shall be pleased to try and help you further.—THE EDITOR.

5775. **Bromide of Copper Intensifier**.—There is no objection so far as we know. The probable reason

for its not being recommended is that it is not generally known.—THE EDITOR.

5782. **Llandudno**.—Can recommend Westminster Hotel, Llandudno; Waterloo Hotel, Bettws-y-coed. Have stayed at both places.—TRIX.

5783. **Mountant**.—Soak separately in cold water equal weights of the best glue and gum arabic. The gum will dissolve altogether, and the glue will swell. Then transfer the latter to a glue-pot, and when it is perfectly liquefied, add to it the solution of gum. Stir it thoroughly, strain through muslin, and bottle off for use. The mixture must be warmed before application to the prints.—P. HARRISON.

5783. **Mountant**—

Soft gelatine . . . . . 200 gr.

Distilled water . . . . . 6 oz.

Soak gelatine in water for an hour. Dissolve by aid of a water bath, and add, in small quantities at a time, methylated spirit, 2½ oz., stirring constantly; allow it to set. Should any spirit separate out, it should be re-melted, and a little more water added. Product should be a pure, milk-white, firm jelly. A little carbolic acid may be added if desired. When required for use, melt by aid of hot water or a water bath. The print can be mounted while damp, and it can be shifted about on the mount, or any excess of mountant wiped off, without leaving any trace on the mountant, even the highly enamel ed ones.—INQUISITIVE.

5784. **Mounting Ilford P.O.P.**—

Gelatine . . . . . 2 oz.

Water . . . . . 2 "

Alcohol . . . . . 4 "

Glycerine . . . . . 4 "

First soak gelatine in the water for six hours, and then dissolve by a gentle heat. Next add the glycerine, and lastly the alcohol in very small quantities, stirring between each addition. Do not allow the gelatine to get too hot, as it soon loses its setting properties. For this purpose Nelson's amber gelatine will do very well. This print is laid face downwards upon a clean sheet of blotting paper, and the mountant applied with a stiff brush while warm. Too much must not be applied, as it will ooze out from the edges. Carefully raise the print, placing it in correct position on the mount, lay over it a sheet of white paper, and go over this with a handkerchief or piece of soft rag, pressing the print well into contact with the mount. Mounted print should then be laid face upwards to dry, nothing being laid upon it while damp.—INQUISITIVE.

5784. **Mounting Ilford P.O.P.**—This may be done by wetting the paper previous to mounting, as I have just mounted some prints that I have had for some weeks. I simply put them to soak in water for about fifteen minutes, and then laid them on a piece of glass, face downwards, and put a piece of blotting paper on the back to take up the surplus water, then pasted and mounted on card, and they did not show the slightest defect—in fact, I could not pick out some that I had just fixed.—J. A. WATSON.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S post if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

A. H. ASTON.—The portrait is slightly over-printed, and the print wants trimming down so as to show nothing but the background. The house is also slightly over-printed, or else printed in too strong a light.

S. BRIGGS (Canada).—The work of individual members of your society would certainly be available for any or all of our competitions.

ISO.—The initialling of negatives will not disqualify you. The rule was made to cope with a particular and flagrant case.

TRIX.—(1) Your query is inserted, but why not purchase a copy of our '92 Annual which will give you all the information you want? With regard to your query to us, we will include in our letter. (2) Write to the City Sale and Exchange Rooms, 54, Lime Street, E.C., asking for their terms for hire, which are very reasonable, and include all the best known makers. Try a Taylor, Wray, Swift, or Optimus. (3) Wash your prints well first, and having made up your bath to 8 oz. instead of 16 oz., and allowed it to stand for twelve hours, warm to about 70 deg. F., and then tone. Patchy toning points to contact of the prints with greasy or dirty fingers. (4) Sunk mounts are admissible, and are most artistic, generally adding to the effect.

F. W. WALTER.—The objection to using a caustic alkali for bromide paper is that it too often causes fog, especially round the edges. A carbonate is better.

MISS R. COLLIER.—All prints will be duly acknowledged in our next issue. Yours was received safely.

E. H. KITSON.—There ought not to be any ill effects from your not fixing completely, provided you at once re-fix in a fresh strong bath.

R. W. SMITH.—Probably you are over-exposing

enormously; you do not say whether the plates were black all over or not. Are you sure you pulled the dark slide shutter out? If the plates are blank like clear glass, this is the only explanation possible: if, however, black all over, then probably you are over-exposing. The print you send is from an over-exposed, fogged negative.

H. F. SINGING.—(1) You might try a rather strong acid and alum solution, though you do not give us any idea of what colour the stain is. (2) For the streaky iron stains, try salts of lemon or oxalic acid one part, salt of sorrel two parts, water fifty parts, and soak the negative in it for some hours, and then wash well. (3) The proper way of mounting gelatin-chloride prints if they are squeezed to ground glass is to paste the back well, then squeeze a sheet of waterproof backing paper on the print, then allow to dry and strip, paste the waterproof paper and squeeze on to mount. If the prints are not squeezed to glass—they ought to mount in the usual way if you give them a soaking for ten minutes in an alkaline chrome alum bath, which hardens the gelatine, and prevents it from being so tacky.

F. SCARFE.—When toning the first batch of prints you probably introduced some impurities into the toning bath which caused the deposition of the gold as a black dust. Decant the solution from the deposit, add a little *aqua regia* to the deposit, and heat by placing the bottle in a water bath, when the gold should be redissolved, and may be used again by neutralising with a little carbonate of soda, and adding the solution you decanted.

Fog. (1) The alum was evidently contaminated with some iron compounds which caused the blue-green colour. (2) Soak the negatives in water, then immerse in

Ferric chloride . . . . . 50 gr.

Bromide of potassium . . . . . 30 "

Water . . . . . 4 oz.

till completely bleached, wash well and then redevelop with ferrous oxalate developer. (3) The white opaqueness looks like the deposition of the silver in a white allotrophic condition which cannot be remedied and which is not harmful. Send us up a negative to see, if you like, when we may be able to answer more satisfactorily.

W. HERBERT.—All prints sent into the Monthly Competitions are retained by us.

E. S. AUSTEN.—If you use an alum bath and allow the prints to dry, and then damp them, you will find no difficulty in mounting, if you squeeze the prints to glass, mount on the back a piece of waterproof backing paper, and then paste over this well. When dry and stripped, damp the mount and squeeze the print down.

WALTON.—Try the following varnish for your films.

Paproyxylene . . . . . 30 gr.

Camphor . . . . . 15 "

Pure methylated spirit . . . . . 2 oz.

Dissolve the camphor in the spirit, add the paproyxylene, shake and filter or allow to settle and decant. If the brown colour is on the negative, and your letter is not quite clear on this point, it is probably due to absorption of some iron salt by the damp gelatine.

H. S. W.—(1) Yes, first make a positive by contact printing, and then from this positive make another negative. Both in making your positive and second negative use eikonogen or pyro and ammonia developer, and try for rather thin, soft results, full of detail and without great contrasts, or else you will lose in quality. Probably you would find 10 sec. at 2 ft. distance sufficient with a candle. (2) The fact that the oxalate crystallises out proves that your water has evaporated, and whilst the oxalate may remain in solution at a high temperature, immediately this falls this salt must crystallise out in part; the only thing to do is to keep the total bulk of your solution up to the original quantity by adding more water. (3) We do not return prints sent in to our Monthly Competition, but if we want the negative, which is very rare, we return the same. Entry form sent on.

W. R. P.—(1) Yes, the ruby light will often affect the eyes; and also if you are using ammonia it will affect the eyes. You can very safely replace your red light by a special orange glass which can be had from Benham and Froud, Chandos Street, Claring Cross; they use it in their Perfection lamp. Also if, instead of placing the lamp opposite you, as is so often done, you place it at the side so as to shield the eyes but still throw light on the table, the annoyance will cease. In many cases, too, want of ventilation in the dark-room has a good deal to do with the ill effects. (2) The keeping power of the stock solution of eikonogen depends a great deal upon the specific formula used; the cause of the blackening is oxidation of the eikonogen. (3) Dissolve your sulphite in the boiling water, add some acid to make it faintly acid, then add the eikonogen; the milky deposit might be lime, thrown down from the water, or a little eikonogen decomposed, and the acid thrown down. (4) Ordinary tin dishes are hardly safe; any colour enamel, preferably white or black, and Aspinall's is the best. (5) The colour screen is a necessary adjunct to isochromatic plates if you want to get the full benefit of their colour sensitiveness, and, except in the afternoon when the light is yellow, it should always be used. We can hardly say that its use tends to reduce contrast, as in some instances it may increase contrast, but in others

it lessens it; it is a far too extensive field to enter upon here. We shall shortly commence a series of articles on this subject. (6) The yellow screen must be fixed firmly at right angles to the axis of the lens; it will not do to hold it in front and let it wobble about. Both the Ilford Company and Messrs. Edwards have very ingenious though different devices to fix the screen, nor would it be a difficult matter to devise one. (7) Mounts may be prevented from curling by fixing them between two little slats of wood, which should curl the mount with the print outside, or it may also be obviated to a great extent by mounting on the back of the mount a sheet of white paper rather larger than the print. It certainly would not do to soak the mounts for two or three days before mounting prints on them; the result would be disastrous in the extreme.

J. THOMPSON.—The mountant may certainly be thinned if tooropy or thick. And your idea of sizing and varnishing the backs of the prints is one that we should think would answer; we have not tried it, but it is feasible enough. On the other hand, you might try an alcoholic shellac mountant, as described in Woodbury's "Gelatin-Chloride Printing."

W. BICKFORD.—You are most fearfully under-exposing and not developing enough; give at least double the exposure, and develop till the plate is nearly black all over.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence.

Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the AMATEUR PHOTOGRAPHER, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques of Postal Orders, made payable to Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 3d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C., who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

**Background.**—For sale, background, interior, new, very cheap.—James, 10, Mount Street, Camberwell Gate.

**Bicycles, Tricycles, etc.**—Juno Safely bicycle, balls throughout including pedals, cost £12 12s., can be seen in London, price £6.—Lugard, Chiswick House, Buxton, Derbyshire.

**Cameras, etc.**—Whole-plate camera, one double back, bargain, 30s.; approval. Send stamped envelope.—D. Padgham, 67, Paynton Road, Silverhill, Hastings.

**Hand-Cameras, etc.**—Automatic hand camera, holds 12 lantern size plates, good single lens, time and instantaneous shutter, finder, quite new, 30s.—S. Lane, Alverne Buildings, Penzance.

Lancaster's Omnigraph, 14s.; Watkins' exposure meter, 9s.—St. Lucy's Cottage, Kingsholm, Gloucester. Underwood's Sphynx hand-camera, euryscopic lens, iris diaphragm, time and instantaneous shutter, focusing apparatus, bellows changer, twelve sheaths, two finders, leather covered and good as new, cost £4 last autumn, will take £3; giving up photography.—Dr. Orr, Newington, Sittingbourne.

Underwood's City hand-camera, quite new, morocco leather, bargain, 26s. 6d.—M. H., c/o Maides, Midhurst.

**Lenses, etc.**—Voightlander 9 by 7 wide angle Euryscope, single, cost £2 15s., £1 15s.; head rest, 7s. 6d.; Lerebours portrait lens, £2 2s.; Voightlander rapid wide-angle euryscope, 9 by 7, cost £7 odd, £6, or offers, or exchange.—Cherry, 40, Great James Street, W.C.

Optimus rapid rectilinear 7 by 5, Waterhouse stops, cost 49s. 6d., bargain, 35s.; approval.—J. H. Godding, 6, Milton Villas, Newbury.

**Sets.**—Half-plate 1890 Instantograph, two double backs, waterproof canvas case, two printing frames, developing tray, 4 guineas, or offers?—W., 17, Streatham Hill, S.W.

For sale, half-plate camera similar to Lancaster's Instantograph, raising front, swing back, rack focusing, four double dark slides, and three fold tripod, in case, 60s.; R.R. lens, Waterhouse stops by Robinson, Oxford Street, 25s.; Farnell's shutter, time and instantaneous 20s.; good condition; reason for disposal.—31, St. Maur Road, Fulham.

1891 Instantograph, quarter-plate, one wood and six Tylar's patent metal slides, lens, folding tripod, instantaneous and roller blind shutters, sling case, accessories, 45s.; pine travelling case for touring, 5s., cost 10s. 6d.; Watkins' exposure meter, 10s.; approval. Want half Instantograph.—Laxton, West End House, Mortlake.

Half-plate Instanto set, good as new, cost 84s., bargain, 67s. 6d.—Merrett, Russell Street, Stroud.

Rayment's patent quarter-plate camera, six double dark slides, Wray's rapid rectilinear lens, 5 by 4, and Grimston's patent shutter, practically equal to new, cost £11, will take £6. With this excellent set I obtained the splendid series of pictures to illustrate my well known lecture on "Life among the Boers and Gold Diggers of South Africa."—Rev. J. H. Riddette, The Manse, Haydock, Lancashire.

Lancaster's half-plate International camera, Silver Ring R.R. lens, iris diaphragms, three Lancaster's double slides and three Tylar's metal, four-fold tripod, solid leather baize-lined case, Optimus finder, focusing cloth, etc., in excellent condition, thoroughly sound, no approval, only wants seeing, cost over 10 guineas, cash £7.—Thomas, "Lanteglos" Glebe Avenue, Enfield.

Lancaster's brass-bound 1891 half-plate Instantograph, double slide, lens, changing box, Thornton-Pickard time and instantaneous shutter, leather case, lock and strap, Tylar's exposure meter, price £5.—W. Kennedy, Hope Cottage, High Street, Ramsgate.

Quarter brass-bound Instantograph, 1891, three double slides, lens, shutter, legs, and sling case, in splendid condition, 50s.—Angear, Polvellan, Yelverton, Devon.

Special bargain! Half plate landscape camera (Underwood's), double back and stand, good condition, 33s.; approval unnecessary.—J. Carroll, Thornley and Dakin, Rawcliffe Street, Blackpool.

Whole-plate camera, nearly new, three double backs, all latest improvements, R.R. and W.A. lenses, by first-class maker, apparatus, etc., complete in case, cost £24, price £14, or offers?—Watson, Clara Cottage, Harvey Road, Leytonstone, Essex.

**Stereoscopic Apparatus.**—Stereoscopic hand-camera, Miller's Adelphe, Wray's rectilinear lenses, Kershaw's shutter, first-class through-out, £8.—Archer, Victoria Park, Wavertree, Liverpool.

**Sundries.**—A gentleman taking a caravan tour would like two others to join him.—F. Moore, Hagley, Hereford.

Exchange four years' "Boys' Own Paper" for Demon camera, bags, enlarging apparatus.—Care James E. Lord, Accountant, Rochdale.

Amateur camera builders. Small well-made lathe, good stand and fly-wheel, £3; number chucks and tools included; a genuine bargain; photograph, with particulars, 2 stamps.—61, Gayhurst Road, Hackney.

**Tripod.**—Whole-plate two-fold tripod, new, perfectly rigid, 8s. 6d.—339, Liverpool Road.

## WANTED.

**Cameras, etc.**—Wanted, half-plate Lancaster Instantograph; exchange Talner 1 and camera, in perfect condition, cost nearly £5.—Scott, 3, Cottleigh Villas, West Hampstead, N.W.

**Hand-camera, etc.**—Wanted, hand-camera, Underwood's City or Sphynx preferred.—Holt, Printer, Rawtenstall.

**Lantern.**—Wanted, good triple or biennial lantern, cheap, or first-class exchange.—James, 25, Brunswick Square, Camberwell.

**Sets.**—Wanted, half-plate double extension camera, slides, and tripod, cheap.—Norrington, 12, Augusta Gardens, Folkestone.

**Tripod.**—Wanted, walking-stick stand, table top.—F. Thornton, 15, Bromley Road, Beckenham.

**Bargains in Cameras and Sets.**—15 by 12 double extension camera, leather bellows, rising and falling front, wide angle movement, fitted three double slides, as new, take £8 8s.; 12 by 10 camera, double extension leather bellows, wide-angle movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take

£5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide, changing box, for 24 plates, also changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; half-plate 1892 Instantograph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; quarter-plate Underwood's instanto, finest order, changing box for 12 ¼-plates, good lens, rotating stops, one slide, folding-stand and case, 35s.; 1891 Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Hand Cameras.**—Swinden and Earp hand-camera, carries 20 quarter-plates, fitted Taylor and Hobson's best rapid rectilinear lens, roller-blind shutters and case, as new, £6 15s.; half-plate Lancaster's Rover, latest pattern, Lancaster lens and shutter, as new, 70s.; quarter-plate Rover, as above, take 42s.; Houghton's automatic hand-camera, carries 12 quarter-plates, rapid rectilinear lens, two finders, Kershaw's shutter, take £3 15s.; Adams' Ideal hand-camera, carries twelve quarter-plates, finest rapid rectilinear lens, two finders, etc., as new, £5 17s. 6d.; Stienheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Optimus defective camera, by Perken, Son, and Rayment, Optimus rapid rectilinear lens, carries six ¼-plates, covered black leather, take £4 4s.; Optimus magazine hand-camera, carries twenty-three quarter-plates, fitted Euryscope rapid rectilinear lens, instantaneous roller blind shutter, two finders, as new, take £5 15s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 17s. 6d.; and another, 15s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, 32s. 6d.; All above warranted in very finest order.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Lenses.**—10 by 8 Lancaster's rectilinear lens, Silver Ring, iris stops, as new, £3 7s. 6d.; whole-plate portrait lens, rack focussing, Waterhouse stops, works 7/6, take 68s.; Ross 10 by 8 wide-angle rectilinear, rotating, fine definition, with flap shutter, £3 10s.; Ross' whole-plate rapid symmetrical, Waterhouse stops, works 7/8, £4 12s. 6d.; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross' actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; whole-plate Suter No. 3, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; half-plate Dallmeyer rapid rectilinear, quite new, iris stops, movable hood, £4 10s.; half Ross' rapid symmetrical lens, as new, movable hood, Waterhouse stops, take £3 17s. 6d.; half-plate rapid rectilinear, by Parker, Holborn, aluminium mounts, as new, take ; Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d.; Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, Corner Leadenhall Street, City (late Goy's Medium).

**GOOD OPPORTUNITY FOR AN AMATEUR** desirous of commencing Business; capital required, £400. Business in large provincial town, returns £400; handsome shop and studio; all apparatus and requirements; carried on by a lady at present; good reason for disposal.—Apply, Reflex, office of this paper, 1, Creed Lane, E.C.

**RICHARDS' Patent Corners**, for mounting photos, prints, scraps, etc., in albums, scrap books, and mounts, clean, convenient, ornamental, self-contained and always handy, ready gummed, price 1s. the box.

It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.

OUT OF POSTAL UNION ..	" " 7s. 9d.....	" " 15s. 3d

TRADE ADVERTISEMENTS are received up to Tuesday morning.

PUBLISHING DEPARTMENT.—All letters containing Subscriptions, Orders, Remittances, SALE and EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZELL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition, No. 39.—  
"SEA PIECES OR RIVER SCENERY." Latest day, August 22nd.—  
Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, September 16th.)

WE again call the attention of the secretaries of photographic societies to the fact that early application is desirable for the 1892 AMATEUR PHOTOGRAPHER Prize Lantern Slides. We hope to be able to complete all arrangements by September 14th, and shall as soon as possible publish the dates and places of exhibition.

THE Bedford and District Camera Club purpose holding a Competitive Photographic Exhibition on October 11th, 12th, and 13th, which will be open to all amateurs. A series of awards will be granted, which will be of an honorary character (with two exceptions, as undermentioned), to the successful competitors, and the Council of the above Society will appoint, to act as judges, gentlemen of standing, whose names will be announced at an early date. A series of lantern-slide exhibitions will also be given in the evening. The following are the rules and classes:—

(1) No charge will be made for space. (This applies solely to amateurs' work.) (2) Intending exhibitors must intimate not later than September 20th the nature and extent of their exhibits upon the official form, which may be obtained from the secretary. (3) Pictures must be framed, and each must have an official label properly filled up attached to it. (4) All exhibits must be sent carriage paid, addressed to the secretary of the above Society, to be delivered at 35, High Street, Bedford, not later than October 3rd, 1892. (5) There will be no restriction as to the number of exhibits which may be sent in. (6) Pictures may be sent in and will be gladly accepted for exhibition only and not for competition, but such limitation must be marked on the back of each. (7) A silver and bronze medal will be given respectively for the two best pictures, irrespective of size, in the exhibition, all of which must be the competitor's own bona fide work. (8) No picture shall be eligible for competition in any class other than the one for which it is intended. (9) The Council reserve the right to select exhibits, to alter any of the conditions, and to withhold any award for which there is not sufficient competition. (10) The Council undertake to unpack, repack, and return all exhibits, but the return carriage must be paid by exhibitor; and while all due care will be taken of the exhibits, the Council will not be responsible for any loss or damage that may occur.

There will be three honorary awards in each of the under-noted classes:—(1) Landscape, 8½ in. by 6½ in. and above. (2) Group subject (quarter-plate). (3) Portraits, 6½ in. by 4½ in. up to 10 in. by 12 in. (4) Genre pictures. (5) Single figure. Studies not to exceed 15 in. by 12 in. (6) Landscapes, 8½ in. by 6½ in. and under. (7) Pictures which have previously obtained a prize. (8) Lantern slides, in sets of six. (9) Instantaneous pictures, any size. (10) Enlargements, any size. (11) For ladies; any subject and size. (12) Special—For boys and girls who are members of the Bedford Schools; any size or subject. (13) Special—A silver and

bronze medal will be given for the two best pictures in the exhibition. Any further information may be obtained of the Hon. Secretary, W. E. Ison, Hughenden, River Crescent, Bedford.

Mr. HOUGHTON, of the Stodart Studios, Broadstairs, has kindly placed his dark-room at the disposal of visitors. The charge is 3d. per diem for changing and 1s. 6d. for developing, with use of all chemicals. Ilford and Barnet dry plates are kept in stock.

Mr. Hamilton of the Wrotham Hotel, Broadstairs, has also a dark-room available, but visitors must provide their own light.

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

WE have been much amused whilst away last week at Broadstairs to hear the remarks made by an amateur of unbounded experience and self-conceit. In talking to a friend at the dinner-table of a boarding-house, he held forth at great length on his high-class work, and his friend, who was evidently only just a novice, was considerably awed and astonished. Very soon the conversation turned to books and periodicals, and our friend of such wide experience said, "Oh, I never take in any photographic paper. There is never anything new in them, only the same old twaddle, which I learnt when I first began." Here a quiet question elicited the fact that he had had his camera only eighteen months! We were, unfortunately, struck dumb at the stupendous wisdom of the gentleman who had mastered photography in eighteen months, and could learn nothing new, and as he takes in no papers he will be no wiser than before. Still, it is just as well to be sure of your audience knowing nothing before you talk too big.

## NOTES ON COLOUR.

### I.—LIGHT.

THE question, "What is Light?" has from time immemorial agitated the minds of philosophers, and various have been the answers given. The ancients considered it possible for the eye to send out long delicate feelers, which rendered man cognisant of the object to which the eye was directed. Sir Isaac Newton propounded the theory which assumed light to be an imponderable, subtle substance, consisting of extremely minute particles of matter, and that these minute corpuscles were emitted from luminous bodies at enormous velocity, and, entering the eye, struck the retina, and produced the impression of vision. This theory, however, was found unsatisfactory, and Huyghens proposed the now universally accepted undulatory theory, which assumes that space is filled by a rarified, elastic substance, which is called the luminiferous ether. This ether is supposed to be also very closely surrounding the molecules of all matter.

The particles of luminous bodies are supposed to be in extremely rapid vibration, and these said particles being surrounded by the ether, a series of waves or undulations are set up in the ether, which proceed at an enormous

velocity. The shock of these waves upon the retina produces the sensation of vision and gives us the impression of light. From a number of investigations the velocity of light is stated to be 300,574,000 metres per second in a vacuum.

The particles of matter which constitute a luminous body bring in rapid motion, impart this motion to the surrounding ether, forming waves which are somewhat similar to waves formed on the surface of still water by the dropping of a stone, proceed in all directions in straight lines, unless they meet with some obstacle, when their behaviour is influenced by the physical character of this obstacle. Thus the waves of light from some luminous body, such as the sun, proceed in straight lines till they meet an obstacle in the shape of a mirror, when they rebound and then reach the eye, having suffered what is called reflection. All substances reflect light more or less, the degree and character of the reflection being altered by the physical character of the surfaces of the object; thus a highly-polished sheet of silver reflects the light incident upon its surface almost entirely—actually 92 per cent. of the incident light; and this silver plate not only reflects the light, but seems, under certain conditions, to press the light closer together, so as to make sharply-defined masses of light. If the sheet of silver, instead of being highly polished, possesses a matt, dead, or rough surface, the inequalities of the surface scatter the light in all directions. The facts just stated about our two sheets of silver apply more or less to all substances, and therefore the connection between the sheets of silver and natural bodies will explain several facts to which attention will be drawn hereafter.

As all substances reflect more or less of the light incident on their surfaces, so all substances transmit, or allow to pass through, some of the light. Taking two examples, such as a thin sheet of glass and a sheet of gold, in the first case we find that the light is transmitted with almost inappreciable exactness of intensity and tint, and therefore glass is said to be transparent and colourless; but in the second case, if the sheet of gold is of the same thickness as the glass—say, one centimetre, we can detect no light passing through it, therefore gold is said to be opaque; but if the sheet of gold is reduced to a very thin film, by a suitable process of rolling and hammering, what do we find now? that it is no longer opaque, but transmits a characteristic bluish-green light. Between these two extremes, none are strictly and absolutely transparent, none are strictly and absolutely opaque.

The question naturally arises, Why is the light transmitted by a thin leaf of gold bluish-green, and not white, as was the light before transmission? An explanation of this will follow later on. The point to which we are now led is this—the objects by which we are surrounded in nature possess each of them a distinctive colour when illuminated by sunlight, and although sunlight is white, yet objects are coloured. To explain this phenomenon, we have recourse to an experiment first made by Sir Isaac Newton. He allowed a beam of sunlight to enter a darkened room through a small hole in the shutter of the window, and obtained a round image of the sun on a screen of white paper, but by placing in the course of the beam of sunlight a prism, or a piece of colourless glass of particular shape, instead of a round image of the sun he obtained, in a different position, a band of different colours blending gradually one into the other. This band of colours is called the solar spectrum. Examining this spectrum carefully, let us note what we can see.

Commencing at the top it is seen to be a deep crimson, gradually brightening into scarlet, and passing without perceptible limits into orange, the orange shading into

yellow, the yellow into yellowish-green, and the yellowish-green into a decided green; these colours are at once striking and of equal intensity as the red, that is to say they are all visibly bright; from the green we pass into greenish blue, from greenish blue into violet, and then the colours end, these last colours are not nearly so bright visually as the others. The beam of light which has passed through the prism has been refracted, and at the same time has suffered dispersion, that is to say, the beam of which light has been split up by the prism into its constituent rays of coloured light.

A natural sequence of thought from the last experiment is as to whether the colours of our spectrum cannot again be split up in the same way by the application of, or a repetition of the arrangement in our first experiment.

Thus, let us arrange our prism so that we obtain our spectrum, but instead of receiving the spectrum upon a sheet of cardboard, as before, allow it to fall upon a card in which is a small slit, and placing this slit in the position of one of the colours, allow that colour to pass through the aperture in the card and fall upon a second prism. The result will be that the rays of coloured light will again suffer refraction, but not dispersion, and that only light of the colour allowed to pass through the cardboard screen will be received upon the second screen, after passing through the second prism. We thus prove by a simple experiment that the colours of the solar spectrum are simple, homogeneous, or elementary, and not heterogeneous, like sunlight.

## Letters to the Editor.

### A TRIP TO CHICAGO.

SIR,—In reply to your correspondent about taking cameras to America, I can tell him from personal experience that he will have to pay a very heavy duty.—Yours faithfully,

CHAS. STANHOPE SMELT.

SIR,—I have to-day read Mr. Harris' letter which appears in your current number. Although I think it probable that I am only one of a large number of your readers who have been to the United States with their cameras, perhaps as one who has just returned from a tour in the States and Canada, and who can therefore speak from recent personal experience, I may be allowed, for the information of Mr. Harris and any of your readers who are interested in the subject, in a few lines to say what that experience was.

During a short tour in the United States and Canada in 1891-92, my camera was six or seven times through the hands of the Custom House officers, but I never was required to pay one red cent of duty. Once or twice an officer did hem and haw a little about it, but on being civilly—and that I may remark is important—assured that it was not new, and was solely for my own use, no more was said about it. Speaking generally, I found the United States Custom House officer a very reasonable being, but resembling other people in authority in that he doesn't like to be bluffed. Inattention to this is the mistake that travellers are apt to make. Judging from my own experience, I think amateurs need have no hesitation in taking their cameras with them when they visit the States; indeed, I consider it probable that any one who does not will regret it afterwards.—I am, etc.,

CHARLES D. RITCHIE.

\* \* \* \*

### HUNSTANTON.

SIR,—In your issue of August 5th, "Trix" asked a question (No. 5780) about Hunstanton and neighbourhood. I do not know of any dark-room at Hunstanton or Snettisham, but at Lynn he will find one at 60, High Street, kept by T. Smith and Son, who stock all sorts of plates, papers, and chemicals. As to objects of interest, in Hunstanton, St. Edmunds, there are the

churches, and some good landscapes may be got in the district. If he takes a walk towards the Convalescent Home he will find that he can get several splendid pictures. But the beach is the paradise of a photographer; studies of boating, fisher folk, and old boats may be had in abundance.

In Old Hunstanton he will find the church and some old cottages, which he must get in the morning. At Snettisham, Heacham, and villages that way, there are only the churches and some old cottages interesting, but if he keeps his eyes open he may get some good harvesting studies during the next three weeks.

When he gets to Lynn he will find the Red Mount (best taken from the back path), the South Gates (best from the outside), the Greyfriars' Tower (back the plate), St. Margaret's Church, and St. Nicholas's Porch (do not miss this, as it is one of the finest in the Eastern counties). There are three minor churches, and good work may be done along the river, especially from West Lynn. When so near, he should continue his journey on to Wisbech, distant fourteen miles. Walking or cycling are the best means of travelling. Each village has objects of interest. West Walton Church should not be missed, and he should enquire for the legends connected therewith. Walsoken Church can be done, and in it is a magnificent font. If he enquires of Mr. Munsen, the sexton, who lives near the church, he will provide him with the key—a silver key will help. As he arrives at Wisbech he will find plenty of work—the churches, Clarkson memorial, Institute tower, the river, and no end of other bits. I may state that I have taken photographs in nearly every church-yard in this district, and have never met with any objection. If admission is wanted to the church, a request to the clergyman will obtain all that is wanted.

A WISBECHIAN.

### A DOUBLE-ACTING PLUMB INDICATOR.

Sir,—I take the liberty of sending sketch of double-acting plumb indicator to be fixed to the side of a camera swing back when there is a reversing back. Being hinged, it can be used either as in sketch, to show when the view is vertical on the focussing screen, or, when folded back to A, to show when the swing back is vertical; and when not in use may be brought over to B so as to protect the plummet, the wood being recessed to clear it.

A. J. ADAMS.

## General and Photographic Chemistry.

By E. C. CONRAD, F.C.S.

### III.—THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.

*Abbreviations Used.*—Syn., synonym; Oc., occurrence in the natural state; M., manufacture or preparation; P., properties; U., uses; U. P., uses photographically; S. G., specific gravity; Eq., equation; Ex., example; C.C., cubic centimetre; Stp., standard temperature and pressure.

All temperatures are expressed in degrees Centigrade, expressed by ° C.

The above elements will be considered in the following order: H, O, N, Cl, Br, I, F, C, S, P, Si., As.

#### HYDROGEN, H=1.

Oc.: Small quantities are found free in the exhalations of some volcanoes and hot springs. It is very abundant in a combined state in water, marsh gas, and in

the bodies of plants and animals. M.: (1) By acting on Zn with dilute sulphuric acid hydrogen is obtained, and can be collected over water. Eq.:  $\text{Zn} + \text{H}_2\text{SO}_4 = \text{ZnSO}_4 + \text{H}_2$ . Iron, aluminium, chromium, manganese, etc., act in the same way. (2) By passing steam over any of the above metals when red hot hydrogen will be set free. Ex.:  $\text{Fe}_3 + 4\text{H}_2\text{O} = \text{Fe}_3\text{O}_4 + \text{H}_2$ . (3) By bringing metallic potassium or sodium into contact with water at the ordinary temperatures hydrogen is produced. Eq.:  $\text{K}_2 + 2\text{H}_2\text{O} = 2\text{KHO} + \text{H}_2$ . P.: It is a colourless, invisible gas without taste, smell, or any poisonous action. It readily combines with oxygen, burning with a faint but extremely hot blue-coloured flame, producing a temperature of about  $3,000^\circ \text{C}$ . In bulk these gases combine with a violent explosion when the mixture is subject to light or heat, such as sunlight, flame, or electric spark. It is only slightly soluble in water, 100 cc. of which dissolve 1.93 cc. of the gas. It is the lightest body known, being 14.47 times lighter than air, and one litre only weighs at stp. 0.0896; if this number is multiplied by the atomic weight of any simple gas, the result will represent the weight of one litre of the gas taken. This number represents the coefficient for weight of any gas, and is called a *Crith.* Gases diffuse at a rapidity that is inversely proportional to the square roots of their densities, therefore hydrogen being the lightest is also the most diffusible body known. It is an essential constituent of all acids and of water. The affinity of hydrogen for oxygen is very great, and their combination always produces water. Most oxides are reduced, when heated in an atmosphere of hydrogen, either to the metallic state or to a lower oxide. Ex.:  $\text{Fe}_2\text{O}_3 + 3\text{H}_2 = 3\text{H}_2\text{O} + \text{Fe}_2$ , and  $\text{Mn}_2\text{O}_3 + 2\text{H}_2 = 2\text{H}_2\text{O} + \text{MnO}$ .

Hydrogen also combines by direct chemical action with Cl, Br, I, and S, and indirectly with all the other non-metals and some metals. Some of the compounds produced are combustible, as  $\text{H}_2\text{S}$ ,  $\text{SiH}_4$ ,  $\text{NH}_3$ ,  $\text{PH}_3$ , etc. The compounds resulting are the same as those which would be produced by the combustion of the individual constituents. Ex.:  $\text{H}_2\text{S} + \text{O}_3 = \text{H}_2\text{O} + \text{SO}_2$ . U.: In combination, by bringing a jet of oxygen into a flame of hydrogen the oxy-hydrogen flame is produced, which is very slightly luminous, but of intense heat (about  $2,800^\circ \text{C}$ ). If this flame is projected on a piece of lime it raises its temperature to whiteness, producing the so-called limelight. By burning magnesium dust in this flame a good artificial photographic light is produced.

#### OXYGEN (O = 16).

Weight of a litre at Stp., 1.4298 grammes. Oc.: Oxygen is found free in the atmosphere, of which it constitutes about one-fifth by volume; and in combination with all the elements excepting fluorine, it is calculated to form  $\frac{1}{2}$  the weight of the earth and  $\frac{8}{9}$  the weight of water. M.: (1) By heating potassium chlorate oxygen gas is given off and can be collected over water. Eq.:  $2\text{KClO}_3 = 2\text{KCl} + \text{O}_6$ . To decompose the chlorate by itself requires a high temperature, the chlorate first melting and then decomposing. (2) If manganese dioxide ( $\text{MnO}_2$ ) is mixed with the chlorate before heating, the oxygen is given off at a much lower temperature, in fact before the chlorate melts, and this constitutes the ordinary method of preparation; the manganese dioxide undergoes no change. (3) Small quantities of oxygen can be prepared by heating mercuric oxide. Eq.:  $2\text{HgO} = \text{Hg}_2 + \text{O}_2$ . The oxides of silver, gold, and platinum act in the same way. (4) Manganese dioxide is reduced to a lower oxide at a high temperature, and gives free oxygen. Eq.:  $3\text{MnO}_2 = \text{Mn}_3\text{O}_4 + \text{O}_2$ ; some other dioxides act in the same way. Oxygen is now manufactured on a large scale from the air, by several methods, of which the following will serve as an example. If dry air is passed over hot barium oxide ( $\text{BaO}$ ), the dioxide is formed  $\text{BaO} + \text{O} = \text{BaO}_2$ , and on stopping the air and continuing the heat

this dioxide is reduced to the monoxide  $\text{BaO}_2 = \text{BaO} + \text{O}$ , so that this method forms a theoretical continuous process. P.: Oxygen is a colourless, invisible gas, without taste or smell. It is a very active body combining energetically with most of the elements, especially with hydrogen and carbon, producing the phenomena of combustion by which we obtain light and heat from wood, coals, gas, and other hydrocarbons. The heat of our bodies is due to the same cause, the oxygen of the air being carried by the blood to the seat of muscular action, and there combining with the elements of our food to produce animal warmth. Oxygen combines with most of the metals, either at the ordinary temperatures or on heating to form oxides, but gold, silver, and platinum will not combine directly at any temperature. The oxides can also be obtained by heating the nitrate or carbonate of the metal. In nearly all cases the heat must not exceed dull-redness, or the metal itself will be left. Carbonates of potassium and sodium are not decomposed by heat. With the exceptions already mentioned, most of the oxides are stable at all temperatures. Hydrogen gas reduces heated oxides either to the metallic state or to a lower oxide, but the oxides of barium, strontium, calcium, and magnesium are not reduced. U.: To produce high temperatures and in combination.

NOTE.—Students will find it to their advantage to buy ready-made the compounds they may require, but if they wish to make small quantities for experiment, the following apparatus will be sufficient:—Two glass flasks of about 5 oz. capacity, with corks to fit, perforated with one and two holes; one of each will do, and indiarubber ones are best; two beakers about 3 oz.; two gas cylinders with glass plates for covers; six test tubes 5 in. by  $\frac{1}{2}$  in., and three boiling tubes 6 in. by  $1\frac{1}{4}$  in.; a thistle funnel, and some pieces of glass tubing (say  $\frac{1}{4}$  lb.) to be bent into required shapes and large enough to fit holes in corks rather tightly; about half a yard of rubber tubing to fit glass ditto, for making joints; and a Bunsen burner or spirit lamp for heating. Unless otherwise stated, use dilute acids and heat gently.

OZONE.—Weight of a litre at stp., 2.15 gm. This substance, which is an allotropic modification of oxygen, is that gas in a condensed condition, three volumes of oxygen becoming two volumes of ozone. Oc.: It occurs in nature in the air, particularly after thunderstorms. M.: It is always produced by the passage of electricity through the air or oxygen gas, and can be prepared by a continuous silent discharge through oxygen. By the action of moist phosphorus on air. P.: Ozone is also produced by combustion, but is decomposed at about  $300^\circ \text{C}$ ., forming oxygen. It has a peculiar smell, always noticed when an electrical machine is in use. It acts on metallic mercury and moist silver to produce oxides. It is very slightly soluble in water. Ozone is destructive to sensitive surfaces and deteriorates apparatus. It is best to exclude electrical apparatus from dark-rooms or stores of photographic goods. Test: A paper moistened with a solution of potassium iodide, and starch is turned blue by the ozone setting free the iodine.

(To be continued.)

An interesting feature of the late rioting and bloodshed at Mr. Carnegie's works was the employment of detective cameras to photograph the rioters unknown to them. The evidence of the plates will probably decide the vexed question as to which party began the struggle and violated the law by entering the grounds of Homestead.

The employees of Messrs. Wood Bros., 73, Lord Street, Liverpool, held their first annual beaneast on Bank Holiday, August 1st, at Douglas, Isle of Man. The day was all that could be desired for such an event, which was well appreciated by all concerned. After a most pleasant voyage across, they all betook themselves to an hotel, where dinner was served up in good style. Several places of interest in the locality were visited during the day, including Port Soderick, The Smuggler's Cave, etc. A good number of hand-camera shots were indulged in on the Paget Prize plate, the results being such as to substantiate their excellence. After a most enjoyable day's pleasure the party returned home by the midnight boat, greatly benefited by this their first outing.

## How to Make a Set of Photographic Apparatus.

By H. J.

### CHAPTER III.

#### A DOUBLE EXTENSION CAMERA (*Continued*).

THE body of camera must be made next, and it can either be made in the same way as that described in the first chapter, or it can be dovetailed; and as the latter is the most workmanlike method, I will give instructions how to do it as well as I can, though it is a rather difficult matter to teach amateur woodworkers who do not understand the various technical terms, etc. However, I will do my best to keep clear of technicalities, so as not to confuse the novice any more than I can possibly help.

The wood of course must be first prepared in the same way as described before, and we shall want a piece about 3 feet long,  $1\frac{3}{4}$  inches by  $\frac{3}{8}$  inch; when this is planed up straight and true, run an eighth of an inch groove on one side, a quarter of an inch from the edge; and then cut the piece into four lengths, two  $8\frac{5}{8}$  inches long and the other two  $8\frac{3}{4}$  inches long. They should be cut off square, as if not, it will be more difficult to make a good job of the dovetailing.

Now take the two shortest pieces and place them face to face, that is, with the two grooves in them together as in fig. 22, and holding them exactly level at sides and ends. Drive in a couple of very fine brads, so as to hold them together temporarily; now with the square and a small chisel, make a mark all round seven-sixteenths of an inch from each end; this should leave  $7\frac{3}{4}$  inches between the marks, which is the size of the finished camera inside.

The dovetails can then be set out as shown, first marking a half dovetail at each edge, and then dividing the remaining space into equal parts. I have shown three complete dovetails besides the two halves, but though the more there are, the better and stronger the work is, still it is more difficult than it would be if they were fewer and farther between, so I must leave it to each one to use his own judgment according to his skill, whether he uses more or less. After setting out the dovetails on one piece at both ends, the marks should be squared over on the end grain across the two pieces, as a guide for the saw; and they can then be cut, using a fine saw and cutting as true to the marks as possible. It will now be plain what my reason was for fixing the two pieces together, as it is very evident that if each one was set out and cut separately, it would be a great chance if they were exactly alike, which is absolutely necessary for good work, and again it would take double the time to do, than it does if done as I recommend.

The two pieces can now be taken apart and the brads withdrawn, and a line can be made on the inside as they were together, connecting the two marks on edges. Now take one of the other two pieces, and fixing it in an upright position in the vice, or holding it so by any means if you have no vice, then place one of the pieces already cut on it, keeping them both level at the edges, and keeping the mark on the edge of top piece just at the inside of the upright piece (see fig. 23), and taking care that the grooves

come together inside; then holding the top piece firmly with the left hand, with the same saw as the dovetails were cut with, mark each dovetail on the end of upright piece; this is easily done by inserting the point of saw in cut and drawing it towards you—the last tooth then makes the required mark.

Each of these two pieces must now be numbered as shown in fig. 23 (1, 1), and then each corner can be done in the same way; the only thing to mind about is, to keep the grooves together inside, and not to mark over again any that have been marked before, or you will be fitting the same piece in two places, and of course at the finish you will have one piece not fitted at all.

Now take the two pieces which have just been marked, and square them all round with the chisel, half an inch from each end, thus leaving  $7\frac{3}{4}$  inches between the marks, as in the other two; then square from the end down to the cut marks which you have just made (these can be marked with a pencil, as they are only guide marks for the saw), and then saw down just *outside* the marks on the ends of the two pieces; if you leave about the thickness of the saw between the marks and the saw cut, you will be about right, but do not leave quite so much on the outside pieces (the half dovetails). Now with a very sharp chisel, and cutting half-way through from each side, cut out the smallest pieces (as x x x x in figs. 22 and 23) in the first pieces you cut, and the larger pieces in the last two pieces; these latter will present the appearance shown in fig. 24 after the waste is cut out. The pins, as they are called (p, fig. 24), should now be slightly pointed by taking off the corners; this is to make them enter their respective mortices better; and then the body can be put together, first glueing the pins with some good hot thin glue.

If properly done it should require a few smart taps with the hammer to get them in (using a piece of wood to prevent the hammer from spoiling the work), and it should all go together firmly so as not to require any nails, and if it does so it can be put aside to allow the glue to set before cleaning it off. While this is doing, make a strip 3 ft long and  $\frac{3}{8}$  inch wide, of the right thickness to fit the groove which now runs round inside of camera body; and when the latter is dry, fit in all round in

the grooves, glueing it in.

The body must now be cleaned off, that is, planed off at the corners where dovetailed; this must be done with a plane set very fine, or you will find some pieces split out. When you have planed it all round, run a small bead round both edges, and this part is finished until it is time to fit the camera up. Now take the sliding front which I described in the last chapter, and after fitting the lens if you have one, make a piece  $\frac{1}{4}$  inch thick and the same size as the small end of bellows, which I will suppose to be 4 inches; cut a hole out of the centre of this for lens, getting it plenty large enough; then place this piece in the end of bellows, and fold the leather or cloth, as the case may be, over

FIG. 22.

FIG. 23.

FIG. 24.

the front, fixing it there with a few very small tacks, and then place it centrally on the sliding front, and screw the two pieces together from the inside. The whole arrangement is shown in fig. 27, and though this is not the way it is usually done, I find it much the best way, as well as being very easy to do, and it is quite light-tight and strong, while the bellows can be easily removed at any time if required.

FIG. 25.

The other end of bellows will be fixed in the camera body in the same way as for the other camera described in Chapter I.; only, as will be seen, there was a rabbit there to take reversing back, and here the slips answer the purpose, so that the strips which fasten bellows are out of sight; and the only care to be taken is, to get the bellows parallel, so that when the camera is open the folds will show even with the body. Now take the front, not the sliding part, but the main frame, and screw on the slotted plate to one of the uprights, keeping it half-way between the brass top piece and the wood bottom piece; then place the wood sliding front in the frame, pushing it down close on the cross piece at bottom, and mark on the sliding front where the bottom of slot in plate comes; take out front again, and insert a plug nut at the mark, then place in position again, and screw a milled-head screw into the nut through the slot in plate, and it will then be found that it gives a very long rise and fall, the front passing up behind the brass top piece, instead of being stopped by it, as

FIG. 26.

FIG. 27.

in some cameras on the market. The complete front is shown in fig. 25.

The camera body can now be hinged to the baseboard; to do this place the two together as when folded (see fig. 28), and place the side hinges on them, without the side stay for the present; this will give the proper place of the parallel piece which fixes to the camera body. When this is found, screw it in its place, then turn the whole over, and fix the one on the opposite side; now place them together again, and mark exactly where the hole comes on the baseboard (this hole is hidden in the figure by the milled head). Take them apart again and insert a plug nut, and this must be inserted at the exact spot; do the other side the same, and then fix each side with a milled-head screw, and try it to see if it opens and closes properly, and if the baseboard is level with the camera all round; if it is not, it can be adjusted by altering the plate on the camera body, or if too bad it can be done by withdrawing the nuts in baseboard and after plugging the holes, inserting again. But if the body and baseboard are both made true and square, there will be no trouble, as it will most likely come right the first time. Having got it right, insert the spare nuts at intervals along each side of baseboard as shown, keeping

FIG. 28.

them the same distance apart on each side. These nuts, I may as well explain here, enable the body to be shifted forward towards the front, by taking out the two milled head screws which hold the hinges to baseboard, and inserting them in the other nuts; this arrangement will be found very useful when using wide-angle lenses, as there is then no fear of half of the picture being cut off by the baseboard, as is often the case where the front is drawn back to get short focus.

The side stays can now be fixed. To do this, first connect the end to the side hinge with the screw, then close the baseboard up to camera, and placing the side stay so that it does not project beyond the back of body, make a mark on the latter at the extreme bottom of slot (nearest the baseboard); and then open the baseboard and insert one of the plug nuts at the mark. Then screw one of the milled-head screws into the nut, through the slot of side stay, when it will be found that the body of camera can be fixed perfectly vertical, whether the baseboard points up or down. This method will be found to give a far larger range of swing back than the arrangement given by me in the first chapter.

The plug nut must be inserted in the opposite side of camera in the same way, the proper place being found by measuring, as they should be both alike.

The reversing back will be made in the same way as the one I described before, with the exception that the clips and clip hinges for holding it in its place will be one top and bottom, instead of at the sides, as I stated then, for reasons which to the makers will be seen; the hinges of course must be at the top and the clips at the bottom. The focussing frame will be also exactly the same in every way, though I must say as I did before, this had better be left until the slides are made, so as to get correct register. The camera can now be blacked inside and polished outside, instructions for which I need not repeat here; but I will caution you not to hurry the polishing, but let it have plenty of time to dry in before finishing, and above all do not be afraid of rubbing it too much, as this is the principal secret of success, to use as small a quantity of polish as possible, and as large a quantity of "elbow grease." If this advice is followed a good lasting shine will be the result, instead of a glitter for a day or two, to go dead after.

The polishing finished, the camera can be mounted. Join the baseboard to the camera (they having been separated for polishing), then take the front frame and insert the two extension rods by taking off the nut and washer; keep the short part of foot towards front of camera, slide the feet of rods in the grooves made for them in baseboard, up to front, and clamp them there by tightening up the top nuts; then slide the camera front into its frame, and screw in the screw in slotted plate. Now try the pinion to see if it will move the sliding part of baseboard forward, which I have no doubt you will find it does; if so, run it back again, and unclamp the front and slide it back inside the camera body. While there screw a small turnbutton on to each upright of front frame, make a small recess in each side of body so that the front will be held in its place. Now fold up baseboard, and screw a small hook and eye on each side at top to hold it there. A brass or leather handle can also be fixed on top for carrying the camera by, unless you intend having a case, when it would not be needed. As will be seen, the camera can be folded without removing lens, if a turntable has been fixed in baseboard; and it would be a very good plan if no turntable is used, to make a hole so that the lens need not be removed in any case.

I hope I have expressed myself sufficiently clear to be understood by all, but if not I shall be happy to answer any inquiries which may be put to me through the medium of the paper or the Editor.

# THE IMPERIAL PLATES

---

SPLENDID QUALITY!  
EXTREME RAPIDITY!

---

Mr. GREEN, of Ipswich, writes:

*"Your Plates have given a grand result."*

---

**POPULAR PRICES:**—Sample box of One Dozen  $\frac{1}{4}$ , or Half-Dozen  $\frac{1}{2}$  Plates, 1s., post free.

---

## THE IMPERIAL BROMIDE OPALS.

Finest and Best.

Rapid and Slow.

Same Prices as our Extreme Rapidity Plates. Sample  $\frac{1}{2}$  doz.  $\frac{1}{2}$  Plates 1/6 post free

---

## Our Thickly Coated Landscape Series ON SELECTED GLASS.

Same Prices as our Extra Rapid Plates. Sample Dozen  $\frac{1}{4}$  Plates or Half-Dozen  $\frac{1}{2}$  Plates 1/3 post free.

THE IMPERIAL DRY PLATE COMPANY, LTD.,  
CRICKLEWOOD, LONDON, N.W.

## ILLUSTRATED SUPPLEMENT,

## Monthly Competition, No. 38, "Inland Scenery, with or without Figures."

## CLASS I.

1. TUCKER, W. H. (Teddington).—"Bagtor Farm, Dartmoor." French R.R.,  $f/22$ ; 4 sec., April, very good diffused light, sun behind cloud, 11 a.m.; matt silver, toned with gold and then platinum. This is a half-plate print of extremely pleasing tone and happy composition. It is brilliant and yet soft, and resembles a good sepia platinotype rather than anything else.

2. SMITH, DOUGLAS (Yorkshire).—"Warwick Castle." Wray's R.R.,  $f/22$ ; about 2 sec., May, good light, noon; Eastman's gelatino-chloride, sulpho-cyanide and gold. "The view is from a private garden opposite the Castle. The negative is too slightly developed for albumen printing, the thick emulsion being deceptive as to density." A very well chosen point of view, and a very fine 12 by 10 print. The light and shade exceptionally good.

3. WILKINSON, S. (Bradford).—"Richmond Castle." Ross' symmetrical, 12 in. focus,  $f/22$ ; 6 sec., June, very dull, 6.30 p.m.; "double printed; the sky cap off and on. When I took this picture the weather was very dull and uncomfortable." A whole-plate print of matt-surface chloride and full of atmosphere and well chosen, with a fine sky effect.

4. TYLEE, C. (London).—"Fishing Station." R.R.,  $f/32$ ; 2 sec., May, good light, 3 p.m. "Thought of getting a print of river with fisherman in, but unsuccessful." A whole-plate silver print full of warmth and breeze, an effect partly due to the rushes in the foreground, and also to the clouds.

5. HAYLES, W. (Cambridge).—"In Ditton Meadows." Wray's R.R.,  $f/12$ ; about  $\frac{1}{2}$  sec., July, bright, light clouds, 3.30 p.m. A whole-plate print, which represents a very happy bit of grouping; had the print been more regular in tone it would probably have come out higher.

6. MCCLEERY, J. (Belfast).—"In Scarva Demesne." Single landscape,  $f/16$ ; 1 sec., May, strong diffused light, noon. A soft, pleasing half-plate matt chloride print, from which just a little foreground could have been spared, and it is questionable whether a better picture could not have been made if the plate had been turned the other way.

7. TUCKER, W. T. (London).—"Llyn Gwynans." June, midday sun; 12 in., R.R.,  $f/16$ ; 1 sec.; Soltype. A very good whole-plate print, but which would have been vastly improved if the cow in the foreground had been out of it altogether.

8. SNOWBALL, G. (Newcastle-on-Tyne).—"On the Common." French,  $f/22$ ; 2 sec., July, diffused light, sun just breaking through clouds, 4.30 p.m. "Taken against the sun, clouds printed in, negative untouched or spotted." A whole-plate matt chloride print which is spoilt by an incongruous figure stuck in the front, and by streaks of dark shade on right hand side.

9. HOLT, HARRY (Liverpool).—"At Gresford." Wray's R.R.,  $f/32$ ; 6 sec., April, good light, 4.30. Whole-plate matt chloride print, printed too deep, and the figures are quite unnecessary.

10. TIMMINS, C. A. (Runcorn).—"Lymm Dam." R.R.,  $f/16$ ; 6 sec., June, bright light, 3 p.m.; platinotype, hot-bath process. A 9 by 7 print, which is completely spoilt by an ugly yellow stain right in the centre of the picture.

11. SMALLRIDGE, C. (Devon).—"A Devonshire Cottage." Optimus R.R.,  $f/24$ ; cap off and on, July, sunshine, noon. A quarter-plate matt chloride print; rather over-printed, and utterly devoid of any brilliancy or sunshine, and not a pleasing tone.

12. CALDWELL, G. (Midlothian).—"The world goes up and the world goes down, And the sunshine follows the rain." Ross' Concentric, 10 in.,  $f/22$ ;  $1\frac{1}{2}$  sec., June, good light, sun strong, 5.30

p.m. A 9 $\frac{1}{2}$  by 7 bromide print, toned with uranium to a very bright colour, which is effective if curious. Had this competitor carried out his title still further by printing in suitable clouds, the print would have ranked much higher.

13. MAITLAND, VISCOUNT (Lauder).—"Evening." R.R.,  $f/16$ ;  $\frac{1}{2}$  sec., March, dull light, 6.30 p.m.; Fry's roughest bromide paper, developed with Rodinal. An 8 by 6 print of very grand effect, and yet which is, unfortunately, utterly false; with such a strong light in the sky and on the water the foreground would have been much lighter.

14. SANDERSON, F. H. (Cambridge).—"The Old Water Mill." Wray's R.R., 6 in., Detective,  $f/16$ ; 4 sec., Easter week this year, soft sunlight, about 4.30 p.m.; albumenised, rubbed down with pumice. A half-plate print of

pleasing tone, which is, however, very weak in the right-hand corner.

15. SUTHERLAND, J. W. (Newcastle-on-Tyne).—"Old Cockington." Optimus 7 by 5,  $f/32$ ; 4 sec., April, bright light, 11 a.m. A half-plate print on matt chloride; rather over-printed, and too much foreground.

16. SCHINWATER, F. A. (Liverpool).—"A Quiet Avenue." Rectilinear, 5 $\frac{1}{2}$  in. focus,  $f/44$ ; 30 min., June, very dull light, 4 p.m.; new cold-bath platinotype. A very good little quarter-plate study, but wanting a little in life.

17. WELCH, J. H. (Liverpool).—"In Birkenhead Park." Wray's 8 by 5 R.R.,  $f/16$ ; quickest time exposure with Thornton P. shutter, May, good light, 4.30 p.m. A soft, pleasing 7 by 5 print on matt chloride.

## CLASS II.

1. PETTY, D. (London).—"Near Hale End." R.R.,  $f/22$ ; 1 min. June, very dull, 3.30 p.m. "Taken on a very dull day while the sun was under rather thick clouds." Half-plate matt-chloride print, wanting in definition at the edges, which gives it a curious vignetté appearance.

2. NICHOLLS, A. C. (Cheltenham).—"A Chat in the Lane." Zeiss No. IV. series,  $f/12$ ; 1 sec., June, diffused light, light clouds, 10 a.m. A 9 $\frac{1}{2}$  by 7 $\frac{1}{4}$  chloride print, in which the figures are so obviously posed or stuck there as to spoil it.

No. 1.]

"BAGTOR FARM."  
(SILVER MEDAL.)

[W. H. Tucker.

3. SOLTAN-SYMONS, G. (Plympton).—"Dairy Dell." R.S., Ross,  $f/12$ ; 2 sec., June, bright, 3 p.m. A 12 by 10 silver print, showing very careful technical work, but almost oppressive from its wealth of detail.

4. HAYES, W. A. (Bournemouth).—"Wimborne Minster." Ross' R.S.,  $f/16$ ; 1-30th sec., June, sunlight, with almost perfectly clear blue sky, 3.40 p.m. A very fine little quarter-plate print on chloride paper, but the horizon cuts the picture in two rather too strongly.

5. BURY, G. R. (Bournemouth).—"Ceriana" Shew's Eclipse,  $f/10$ ; snap-shot, about 1-16th sec., March, bright sun, 2 p.m. "Clouds from same negative." A brilliant little quarter-plate view in Italy; a little too dark in the left-hand corner, though.

6. LINNELL, L. H. (Stretford).—"Near Alderly Edge." Wide-angle landscape,  $f/30$ ; 2 sec., July, diffused light, 4 p.m. Half-plate silver print showing good technical work.

7. SPILLER, A. L. (London).—"The Mill, Pangbourne." Swift's rapid Paragon,  $f/16$ ;  $1\frac{1}{2}$  sec., July, fair, 4.30 p.m. A whole-plate platinotype print, a great deal too black, and wanting clouds.

8. FIELD, A. (Notting Hill).—"The Old Mill House and Salmon Pool." Morley's R.R., 7 by 5,  $f/16$ ; shutter, slow, June, bright at intervals, 11.30 a.m. Over-printed half-plate on chloride paper.

9. SEEVERS, J. (Kendal).—"Grasmere." Beck's R.R.,  $f/22$ ; 1-30th sec., June, bright sunlight, 12 noon. "The negative is entirely untouched." A nice little quarter-plate print, unfortunately a little over-printed.

10. FOSTER, P. S. (Halifax).—"A Misty Morning." Ross' 9 by 7 R.S.,  $f/32$ ; 3 sec., June, good light, 12 noon; platinotype, new cold bath. "There was a good deal of mist about which prevented me getting a good view of the distance." A very good effect has been obtained, but the telegraph post and fence in the foreground are not needed.

11. BIBBY, W. H. (Blackburn).—"A Sultry Evening." R.R.,  $\frac{3}{8}$  in. diameter; 3 sec. June, moderate light, oppressive atmosphere, 7.30 p.m. Half-plate print, rather wanting in brilliancy, and the composition is rather too central.

12. CLEMENCE, H. (London).—"A Devonshire Road." Wray's rectilinear 8 in.,  $f/32$ ; 2 sec., March, sunshine, 4 p.m. A half-plate matt chloride, wanting in brilliancy, and the horse and cart are too central.

13. HARVEY, C. J. (Kidderminster).—"Habberley Valley." Single,  $f/30$ ; about 3 sec., July, bright sunlight, 7.30 a.m. A pleasing little quarter-plate Alpha, print which would be improved by clouds.

14. JUDSON, T. B. (Worcester).—"A Still Pool." Optimus R.R.,  $f/32$ ;  $2\frac{1}{2}$  sec., April, sunlight, 3 p.m. Half-plate chloride print rather over-printed and unequally toned.

15. BAINBRIDGE, G. B. (Northumberland).—"Evening, Derwentwater." Mawson's 7 by 5 R.R.,  $f/22$ ; 3 sec., April, medium light, 6.30 p.m. A very fine evening effect, not too deeply printed, and half-plate matt chloride.

16. MOSS, C. (Sydenham).—"Twilight." R.R. (Watson's),  $f/11$ ;  $\frac{1}{2}$  sec., July, fair but cloudy, 5.45 p.m. A soft evening effect, which would be improved by a little less foreground even now.

17. BENTLEY, A. (New Barnet).—"A Quiet Evening." Optimus 7 by 5 R.R.,  $f/32$ ; 4 sec., May, strong diffused light, 6.30 p.m. Technically a good half-plate silver print, but spoilt for want of clouds.

18. GEDDIS, A. M. (Dublin).—"Glendalough." R.R. 11 in. focus,  $f/16$ ; 2 sec., August, dull, 3.30 p.m. A whole-plate bromide, which is spoilt by a curious dark shade on the right-hand of print.

19. RAMSDEN, W. (Farnworth).—"Bod Owen." Landscape,  $f/32$ ; 1 sec., June, cloudy, occasional gleams of sunshine, 3.30 p.m. "The clouds in print are on negative, but as they print too dark it was

necessary to block them out for about the time it took to print the foreground." A very good half-plate print on chloride paper, but a little too deeply printed.

20. TOWNSEND, C. W. (N. Wales).—"A Quiet Pool." R.R.,  $f/2$  5 sec., June, diffused light, 4.30 p.m. A half-plate chloride print which is too dark in tone on the right-hand side.

## Amateur Photography in America. \*

BY CATHERINE WEED BARNES.

It will be impossible to enter fully into the question of amateur photographic work in America, and I shall not attempt it, but in considering a subject which necessarily involves comparisons between English and American work and workers it is well, in all fairness, to have some clear idea, to start with of how photography is pursued, and the opinion entertained of it in both countries. At present, and this is said advisedly, the English have the advantage at exhibitions of a higher general average of work, though I do not know if it is the case, as with us, that many good pictures never reach the exhibition hall.

The amateurs in England and in Europe generally seem to believe in what they are doing, and consider it worth while to give the work proper time and care, working hard if need be to ensure good results, and this is half the battle. There are too many what might be called snap results with us, and the camera is still looked upon largely as a means to kill time, not worthy of respect for its own sake. We are too anxious to do things quickly, missing often thereby what only comes from patient, long-continued effort. There are instances among our workers of almost infinite patience and determination to show what photography can achieve in art, science, and general education, and such are filled with an enthusiasm which enables its possessor to think only of the end in view, and bend everything to accomplish it, regardless of mental or physical fatigue. The old painters were ignorant of many of our modern canons of art, but they had a worship for the thing itself, too often wanting in our utilitarian age, and the same may be said of photography. Altogether too many workers begin and end with "detective" cameras. Why? Because there is a delusion abroad in the land that they are no trouble, require no brain exertion, are always available, and the user need not look upon his instrument as anything more than a toy. He generally expects, however, that same toy to possess all the photographic virtues of the widely differing branches of work. Beginning with clean, well-lighted portraiture, for instance, through the gradations of soft, atmospheric landscapes and marines, brilliant snap-shots and carefully managed interiors, it is expected all these may be made in the fraction of a second, and, of course, with a single view lens and cheap camera. I once received a letter, not at all an unusual one in my editorial correspondence, wherein the writer took several pages to explain what he wanted a lens to do, each requirement contradicting some other,

and asked me to recommend a cheap one. My answer was that no such lens had yet been invented. The American worker, especially in small towns, is very often unable to purchase more than one lens, and yet is anxious to cover the whole photographic field. In such cases I always discourage hand-cameras, as, under the best of circumstances, their results cannot fairly compete with tripod work, not merely because the latter is better in itself, but after taking the necessary trouble of setting up such a camera one is apt to take more pains with the picture. Until one realises all the possibilities of time exposures he does not begin to appreciate photography at its true value. A very encouraging sign of progress with us is the increasing number of organisations devoted to camera work. Hardly a week passes that a new one is not started; and their reports, as sent to our sanctum, show a constantly widening horizon of comprehension regarding the different fields of photographic usefulness. Physicians, painters, scientists of all kinds are utilising the help photography can give them, and are realising also, aside from that, the great and almost mysterious fascination it can exert, independently, on its own special account. A celebrated painter told me recently that he occasionally used an ordinary snap camera, not daring to attempt any of the actual work or he should neglect his regular painting. I cannot but feel that to do camera work well, through all its countless ramifications—and what is worth doing at all is

worth doing well—one must get rid of, and put behind him once for all, the idea that its limitations are as narrow as the illiberal prejudices of the past have settled upon. It is far harder to live down a prejudice than a principle, and that is just the task that lies before photography.

Experience, however limited, has taught me that when a certain effect is gained in photographic work which at all departs from an ordinary photograph, if one attempts to help others by telling how it was done, his effort is looked upon as if he took his auditors behind the scenes at a theatre, and showed them how certain theatrical effects are produced. Probably the same thing is true this side of the Atlantic. A camerist should, above all things, never apologise for anything which will improve his results, because negative or

No. 3.]

"RICHMOND CASTLE."  
(CERTIFICATE.)

S. Wilkinson.

print has been, as the unregenerate term it, "doctored." If a painter refuses to recognise the existence of an obnoxious element which would spoil his picture, and simply leaves it out, why cannot the photographer use the only means at his command and obliterate the object, whether on negative or print? Why should one be considered genius and the other a trick? The American public, as yet, has not been able to realise that photography has risen far beyond the high tide mark of a generation ago, indeed that it is still rising. They are, as a rule, more anxious for something new than for steady progress in the work, but attendance at recent exhibitions has proved to me that photography is winning a high place for itself, if its followers will insist on not lowering its flag to the level of a trade, but keep it where it belongs, among the arts and sciences which are elevating the general education of the world.

One great cause for the success of European workers at our exhibitions is that we do not give enough consideration to the choice of a subject. We have not the wealth of historic scenes which the old world furnishes, and landscapes, *per se*, pall on one's attention in large numbers, but we are doing something. I am proud to say, to preserve a record of the historic landmarks we own, before the so-called march of improvement destroys them, to say nothing of also keeping a record of passing events, which afford an important field for camera workers. One of the societies with which I am connected has an historical section, whose members are detailed, when any specially important event occurs, to photograph it from different standpoints, thus obtaining a large and varied collection of prints in a comparatively brief time. About a thousand negatives were thus

obtained at the centennial celebration of Washington's inauguration as President, which will eventually be of great value. This society's badge entitles the holder to entrance within the police line at fires, parades, etc., and to work in the city parks. Both the large New York societies also give their members special privileges. This idea as to historical work is spreading among our societies with excellent results. The Chicago workers ought to take up seriously the matter of photographing at the exposition, and a general protest is likely to be made against what appears to be the somewhat arbitrary ruling of the authorities. Permission should not be indiscriminately given, but under restrictions.

I have not been able to procure statistics as to the number of clubs in our country, but have visited many of the leading ones from New York to California, finding that, as in the case of the Boston Club, with its fine studio and meeting-room, each has some special advantage, but none offer better working facilities than the New York and Philadelphia Societies. The New York Camera Club talks of a special club-house, with separate studios, dark-rooms, etc. A desire is spreading among the clubs for more practical instruction than is given in papers or discussions, and nowhere is this better shown than in some of the smaller clubs. The idea, so general here, of camera trips during the summer is also gaining in favour with us. Women are admitted to membership in the greater number of our clubs, and in some of those who still hold out in the good old way their work is hung at exhibitions, their lantern slides shown on the screen, and I have spoken before several clubs which do not as yet admit women members, agreeing, perhaps, with a gentleman friend of mine in one such club, that a photographic society should be con-

of all, making it lighter, carrying the latter point even to excess. English cameras, unless of specially seasoned wood, are apt to warp in our dryer climate, and I do not believe in, and certainly never saw, a single American worker using a wooden slide in his plate holder.

Most of our finest cameras are made to have the ground-glass keep its position, even when the holder is slipped into place, and the tripod top is made distinct from the camera, which latter I am not sure is an advantage.

Practical demonstrations and clear plain talks seem to be most enjoyed at our society meetings, and when papers are read it is a rare case when the lecturer is not afterwards called upon by different hearers to explain various points still farther.

Dry plates are most generally used, though a few cling persistently to the wet process. One amateur I know of who coats all his lantern plates, and another in preparing his takes into careful consideration the special purpose for which they are to be used.

Only a few of our manufacturers make slide plates, and I consider it as somewhat unwise to make them more rapid than English ones, which actual demonstration has proved to me is the case. It is claimed that slide-making is losing in interest, but such entertainments are always well attended, though the audiences seem to pay more attention to the subject of the slide than to its technical or artistic merit. We trust that European workers will in time see the advantages of our size negative and slide-plates and that there is no actual need of using such very heavy cover glass. International exchange of slides is an idea worthy of cultivation, and is of value specially in encouraging all to do their best. Several of our amateurs have ex-

perimented in camera making, and of shutter attachments there is no end. Our national fondness for haste has found a new vent in a kind of craze for instantaneous (I use the word under correction) pictures of racing, athletics, scientific experiments, etc., but, on the other hand, that same tendency leads us to constantly invent practical, labour-saving appliances wherein I claim we hold high rank, and many of our best workers have either personally made many such or suggested them to some manufacturer, while one amateur has invented a shutter which allows several exposures per second. Orthochromatic work (or, I should rather say, colour-sensitive) is receiving more attention than formerly, as the plates improve. They were supposed to be very difficult to develop, but at some of our recent exhibitions remarkable results from them have been shown, especially as regards flowers and delicately-tinted drapery. As is well known, Mr. Ives is the only one among us who has succeeded in demonstrating what is hoped for from colour photography, but even yet he has a difficult task before him. Ordinarily, we depend for our finest lenses on foreign makers, but there has been a new one placed recently on our market by a New York amateur which, in the way of reducing harsh contrasts and allowing the shadows and half-tones to appear as in the gradations of nature, practically enters the field of orthochromatic work. It has a violet-colour attachment which can be screwed into the place of the rear combination of the maker's rapid rectilinear, wide-angle, or portrait lenses.

It slightly increases the time of exposure, and the eye is at first disturbed by the use of the coloured, instead of the colourless lens, but the results are remarkable, especially with portraits. The makers are also busy with a tele-photo lens similar, in some ways, to Dallmeyer's and Miethe's.

There is a reluctance with us, as in England, except among those amateurs who have been given over as incurable, to carry a size camera which will permit the picture to properly represent the view photographed. Even when intended for use in the lantern, the picture takers too often prefer contact slides, simply, it would seem, because their physical strength is really or apparently inadequate to the carrying an 8 by 10 or 5 by 7 camera for the negatives, to say nothing of the extra exertion of reduction, but as the French proverb says, "That which costs nothing is worth nothing." With regard to developers, many of us like hydroquinone, more still like it mixed with eikonogen, and others eikonogen alone, though I believe the majority, for regular work, prefer pyro and soda, as ammonia does not seem to agree with our plates. It would seem a good plan to test each new developer as it appears, for then, and only then, can the worker be really justified in making a choice. A number of our workers are expert chemists, and always prepare their own developers, not pinning their faith on 10 per cent. or any other made solutions. As one of our writers has said, "A fool or a folly is no better for being an old fool or an old folly," and if any method of work or modification of it suits our purpose, we do not wait until it is overgrown by the mass of tradition before recording our acceptance. Film rolls are much used in hand-cameras, though maga-

No. 4.]

[C. Tylee.

sidered merely as a sort of masculine boudoir. Women workers are increasing rapidly among us, and it is only a question of time when they will be generally recognised as mentally fitted to improve the educational opportunities afforded by a club. Working by one's self encourages a narrow prejudiced manner of judging one's methods and results, and women as well as men need to have their rough edges taken off by the sharp attrition of severe criticism and discussion. We have in America what we call smoking concerts, which women, even if active members, do not attend, and it is only occasionally that a pipe or cigar is seen in the ordinary meetings, never at general entertainments. In the dark-rooms the stall system is largely used as being more private, but the printing and slide work is done in a large room. Quite a number of our leading workers have their own developing rooms, and even portrait studios. In my own case, after making a portrait exposure and developing the negative, I take it to a professional friend of mine, who retouches when necessary, and then, unless in special instances, the sitter orders from and pays him for what prints are desired, the negative, of course, being held by me. I have not time to make so many prints, and sitters would not realise the extra labour involved, besides valuing the pictures more if obliged to pay something for them.

In landscape work the English have the advantage, rather than disadvantage, in their unduly blamed climate, far better atmospheric effects being gained than in our clearer air, but they, as a rule, use heavier cameras than Americans. We rarely use an imported one a great while before beginning to make improvements in it, and, first

zines are preferred by those who keep to glass plates, and their number is increasing. Albumen and other glossy surface prints have been most generally used, though they are being superseded with our amateurs by the various matt-surface papers, especially bromide and platinum.

The question of exhibitions is not yet considered, as it should be, a valuable factor in photographic education, and we do not have enough of them. I cannot but wonder sometimes that judges are found willing to face the almost certain blame attaching to them, no matter how conscientious they may be. They are fallible, very much so, like most of us, and naturally praise what seems good to them, whether the general verdict agrees with theirs or not. The true benefit of an exhibition is gained when one ascertains not merely wherein his work excels, but wherein it is deficient. The general impression is growing that boards of judges should not be formed exclusively of either photographers or artists, as each is apt to be influenced by the prejudices of his own special education.

When will it be understood, both sides of the Atlantic, that photography in its dual nature of art and science is not necessarily a house divided against itself, and why is it not possible, as in the story of the gold and silver shield, to look at the question from both sides? Americans have not shown their full strength at European exhibitions, largely because notices of such rarely reach us in time for us to prepare and send any special work, and some international arrangement ought to be made, certainly on our side, to obviate the annoying delay in the Custom House. But I do not propose to discuss the tariff question.

Photographic literature should not be entirely passed over, and its importance is shown not alone in journals especially devoted to its interests, but by the way in which it is leavening our whole American literature. The daily press in many cases publish a photographic column, constant references are made to the subject, and many of our magazines give considerable space to articles on the work, or illustrate their pages from the results of the camera. Even the way in which the newspaper reporter attempts to be humorous on the subject shows a general interest in it. We have several magazines devoted to photography, professional and amateur, and they have a wide circulation. Our readers demand a great deal, being very particular also how it is presented, and those who undertake to furnish food for the average photographic brain have by no means an easy task.

It is often asked me if photography is not dying out, but I can most positively declare that with us it is most constantly growing. There are almost daily enquiries of everyone who is supposed to be an authority, as to instruments and methods of work, and it rests with our great army of amateurs to make their own place in the world.

Believe in what you are doing, and people will believe in you. The work should be followed not merely for personal credit, but for the work's sake and its value as a mental and moral education. I am glad that America has several representatives at this Convention, feeling it will do much to strengthen the bond of comradeship between kindred bodies of workers. There should be only a sense of generous emulation on each side, and the tie of relationship not be weakened, though the ocean lie between us, for each can and should gain by mutual help.

As our great poet Lowell says:—

"For mankind are one in spirit, and an impulse bears along,  
Round the earth's electric circle, the swift flash of right or wrong;  
Whether conscious or unconscious, yet Humanity's vast frame  
Through its ocean-sundered fibres feels the gush of joy or shame—  
In the gain or loss of one race all the rest have equal claim."

## The Theory of Development.\*

(Continued from page 94.)

### IV.—THE ACTION OF LIGHT ON SILVER HALOIDS.

By H. B. BAKER.

It seems to be impossible that the darkening of silver chloride under ordinary circumstances can be due to the formation of a sub-chloride, as this darkening does not take place if oxygen be excluded. Moreover, in a recent communication to the Chemical Society, I have shown that silver chloride may be exposed to sunlight under pure carbon tetrachloride for two months without undergoing any change in colour.

Captain Abney stated some time ago that silver chloride does

not darken in a vacuum, but that if a drop of mercury be present the darkening takes place. I have repeated this experiment, but with opposite results—no darkening whatever taking place. Under liquids which can act as reducing agents, darkening takes place at once, but the darkening is due to the formation of metallic silver. When the silver chloride, darkened in air, is treated with chlorine, oxygen is given off; when it is heated in hydrogen, water is produced; when it is boiled with potassium chloride solution, potash is produced: all facts which point to the conclusion that an oxychloride of silver is formed. The absorption of oxygen by the darkening chloride has been measured, and I have come to the conclusion that the formula is probably  $\text{Ag}_2\text{ClO}$ .

By keeping the darkened chloride together with oxygen in the dark, the colour disappears and the chloride becomes white, a further absorption of oxygen taking place. This change takes place more readily in red light; the white substance is probably a white oxychloride, containing more oxygen than the dark oxychloride. It darkens slowly when treated with developers, and is soluble in fixing solution. It is possible that cases of over-exposure and reversal may be explained by the production of this white oxychloride. Experiments are now in progress with the view of finding out if this is the case.

### V.—NOTES ON PROF. H. E. ARMSTRONG'S PAPER, "THE THEORY OF DEVELOPMENT."

By C. H. BOTHAMLEY.

The electrolytic theory of development is, of course, not new, but it will probably meet with less neglect in consequence of Prof. Armstrong's able exposition. That so-called electrochemical actions should take place in the process, seems on the face of it so very probable, that there is all the greater necessity to point out that the experimental evidence is at present contradictory. On the one hand we have Eder's experiment of developing an image right through a very thick film, considerably further than the light could have penetrated; Eder's experiment of placing silver wire in contact with an unexposed film in a developer, and obtaining a developed "image" at the points of contact; and Abney's experiments, in which the image on an exposed gelatino-bromide film was made to grow into an unexposed collodio-bromide film placed in contact with it. On the other hand we have Hurter and Driffield's conclusion that no electrolytic action takes place at all. In fact, it is clear that if Hurter and Driffield's results are correct, no electrolytic action does take place. Whilst I consider that their results require independent experimental verification, it may be of interest if I state that I have failed to obtain any experimental evidence that

\* From the Camera Club Journal.

electrolytic action does take place in the development of an exposed gelatino-bromide plate. I have not succeeded in repeating Eder's experiment with the silver wire, nor in getting any growth of an image in an unexposed gelatino-bromide film placed in contact with an exposed gelatino-bromide film. The failure may be due to want of experimental skill on my part, and I do not in any way regard the results as final. My belief in the electrolytic theory of development, although at one time strong, is, however, now very much shaken, and I hold with Prof. Armstrong that further experiments are greatly needed.

In a paper on the Latent Image, read at the Conference in 1891, I pointed out that, assuming the electrolytic theory to be true, the formation of the developed image of metallic silver takes place in three distinct stages (1) the formation of a *latent photo-image* by the action of light on the sensitive film; (2) the formation of a *primary image* by the action of the developer on the latent image; and (3) the formation of the *developed image* by the action of the developer on the primary image, and the unaltered silver bromide that is in intimate contact with it. It is in respect of this third change that I now regard the evidence as inconclusive. If this change takes place the image must of course grow laterally as well as downwards, and the marvellously fine detail obtained in many negatives seems to me to be almost positive proof that this lateral growth, or what is practically the same thing, this electrolytic growth of the image, takes place to a comparatively unimportant respect, if it takes place at all.

With the general nature of the chemical change resulting from the action of the developer, I am practically in agreement with Professor Armstrong, and may perhaps be excused for pointing out that I advocated a very similar view at the Conference in 1889. I am, however, quite unable to accept the view that the solvent action of the ammonia plays any important part in the formation of the developed image, and my reasons have already been given in my Conference paper.

I am unaware of any evidence in favour of the hypothesis that the latent image formed by the more refrangible rays is different in character from that formed by the less refrangible rays. The supposition that a silver oxyhaloid would probably resemble silver oxide in its instability also seems to me to be contrary to the weight of the evidence. Certain it is that darkened silver chloride is not affected by many re-agents that would speedily act upon the oxide.

My own experiments led me to conclude that the soluble bromide plays a less important part in the formation of the image than Prof. Armstrong seems to attribute to it, and than, in fact, is generally supposed (*Photographic Journal*, 1890). Doubling or trebling the amount of bromide within certain limits has very little effect indeed beyond reducing the tendency to produce general fog.

Prof. Armstrong rightly lays stress on the need for further research, but with reference to his suggestion that collodion should be used as a medium I beg to point out that the gelatine process is the important negative process, that what we most want to know is what goes on in a gelatino-bromide film, and that experiments made with simple and inactive supports can only afford indirect, and perhaps misleading, indications as to the changes in the presence of a complex and active substance like gelatine.

[The foregoing paragraphs were written very hurriedly at the request of the Hon. Secretary after I had read only Prof. Armstrong's paper at the Conference. I have since had an opportunity of reading Prof. Armstrong's further "Note on Reversal," Capt. Abney's "Notes" on Prof. Armstrong's paper, and the remarks of Mr. Elder and others in the discussion at the Club. As I understand, however, that the foregoing paragraphs have been sent in proof to others who are contributing to this discussion, it seems better to allow them to stand as they were originally written, and to explain somewhat more fully my views on some of the points referred to.]

The experimental evidence seems to me to show conclusively that the production of the latent image on a gelatino-bromide plate is a photo-chemical change, resulting in the production of a compound that contains less bromine than ordinary silver-bromides, and is more readily attacked by reducing agents. I hold, further, that the bromine lost by the silver-bromide is taken up by the gelatine. By the action of bromine on gelatine

it is easy to obtain products containing more than twenty-five per cent. of bromine, but the chief point of interest is the extreme rapidity with which gelatine absorbs bromine in the early stages of the reaction. The phenomena, in fact, indicate that the product in the early stages is an additive compound, and not, as Dr. Hurter assumes (*Photography*, 1891, p. 136), a substitution derivative. This attraction of gelatine for bromine I regard as one of the chief causes, *inter alia*, of the great sensitiveness of gelatino-bromide plates.

Whilst I have been unable to obtain any evidence of electrolytic action in the development of gelatino-bromide plates, and my belief in the occurrence of such action has naturally been shaken, I am bound to admit that if Hurter and Driffield's results could be left out of consideration, the balance of evidence would be decidedly in favour of electrolytic action. The invisibility of the latent image is generally regarded as proof that the amount of material composing it is very small in comparison with the quantity of reduced silver resulting from development. So long as it seems probable that the latent image is similar in composition to the darkened product obtained by the prolonged action of light, this

argument will remain very weighty. It is not impossible, however, that the material of the latent image is similar in colour to the unchanged silver bromide.

It is not impossible to reconcile the occurrence of electrolytic action with the rendering of minute detail to which I referred in a former paragraph. The granular structure of a gelatino-bromide film is well known. Each particle of silver-bromide is intimately associated with some gelatine, the association most probably being molecular in character, but each particle of the bromide is separated from neighbouring particles by a layer of gelatine that contains no silver salt. If we assume, as seems most probable, that the electrolytic action does not spread across this intervening layer of gelatine, but is confined to those particles, some molecules of which have been altered by light, then it is easy to conceive that the lateral spreading of the image might be so small as not to obscure the fine details. This hypothesis is in agreement with the well-known fact that plates with a fine grain are necessary for the rendering of line subjects and minute detail. If, however, the restriction holds good, it

No. 6.]

"IN SCARVA DEMESNE."

[J. McCleery.]

does not seem *necessary* to assume electrolytic action at all, and Captain Abney's hypothesis of the successive formation of silver sub-bromide by the action of the reduced silver on the bromide with which it is in contact, the sub-bromide being continually reduced by the developer, is sufficient to explain the facts. It may be of interest to point out that Captain Abney's view is greatly strengthened by the recent isolation of the sub-salts of silver by Guntz.

Returning now to the question of the action of ammonia in the alkaline developer, and more especially to the part played by the solvent action of ammonia on the silver-bromide, I naturally regret that Prof. Armstrong attaches no importance whatever to my statements on the subject. Prof. Armstrong, however, is not entitled to assume that I forgot that the silver-bromide was wrapped up in a colloid bag. I did not forget. On the contrary, I had constantly in mind the fact that in gelatino-bromide emulsion the silver-bromide is enclosed in a colloid, and, moreover, remains enclosed in that colloid throughout all the operation of development. In view of the well-known fact that silver-bromide under these conditions is less easily acted upon by reducing agents and other re-agents, it seemed, and still seems, to me to be of importance to ascertain whether ammonia of the strength used in the alkaline developer does actually dissolve silver-bromide from gelatino-bromide emulsion. Although the silver-bromide is wrapped up in the colloid gelatine, this colloid is readily permeable, a fact shown by the rapidity with which plates can be developed and fixed. There is therefore no question but that if the silver-bromide were dissolved at all, it would pass through the gelatine into the surrounding liquid, especially when the time of contact was so long as in my experiments. The fact remains that ammonia of considerably greater strength than can safely be used in alkaline development dissolves a barely recognisable trace of silver-bromide from gelatino-bromide emulsion after much longer contact than in ordinary development. In presence of quantities of a soluble bromide such as are used in developers, not even a trace of silver-bromide is dissolved.

I have made, at one time and another, scores of careful experiments on the influence of varying proportions of ammonia and soluble bromide in the pyro-developer, and my conclusions, most of which I have stated before, in various papers, are as follows:—

(1) So far as regards the development of an image in those parts of the film that have been affected by light, the ammonia developer does not differ from those in which there is no suspicion of any solvent action on the part of the alkali.

(2) That as soon as the ammonia is used of such strength or with so low a proportion of soluble bromide that it does exert a solvent action on the silver bromide in the film, then at once general fog begins to be produced and silver is deposited on the exposed as well as on the unexposed parts of the film.

(3) The ammonia developer differs from other alkaline developers, not in the mode of production of the image but in the much greater tendency to produce general grey fog, green fog, etc., the solvent action of the ammonia being the chief active cause in the production of these fogs, but not of the true image.

The occurrence of silver compounds in solution in an old pyro-ammonia developer, as reported by Professor Meldola to Mr. Elder, is quite in accordance with my results. It is very common indeed for the pyro-ammonia developer to be used of such composition that it produces distinct general fog, because, as I have already stated, it does dissolve some of the silver bromide in consequence of the strength of the ammonia or the small proportion of soluble bromide used.

With regard to Mr. Elder's most interesting remarks, I will simply point out that the active constituents of the developer are always present in relatively very large quantities compared with the amount of silver salt that is produced, even when the reduction attains its maximum.

As regards reversal, the explanation given by Meldola in his "Chemistry of Photography" seems to me to be the most rational and satisfactory that has been yet proposed. It may be of interest to call attention to H. J. L. Rawlins' experiments (*J. Soc. Chem. Ind.*, 1891, 18), which lead him to the conclusion that it is practically impossible to obtain second reversal. I have tried many times myself but have never got any indication of such second reversal.

# VL.—NOTES ON PROF. H. E. ARMSTRONG'S PAPER, "THE THEORY OF DEVELOPMENT."

By CAPTAIN W. DE W. ABNEY, C.B., R.E., F.R.S.

To clear the ground in reference to the theory of alkaline development, it is well to take into account two distinct actions which may occur during its accomplishment. In the first place, if we have pyro and ammonia present, it may happen very well that the first shock of development is very similar to that of the wet process, viz., a solution of the silver salt. Weak though the solution of ammonia may be, it will dissolve an infinitesimal amount of silver, and the pyro will tend to reduce and deposit it on the parts which have been changed by light. What I have called the formation of a nucleus for the silver to deposit upon is necessary, and it is very likely that the silver which can be much more easily separated from a solution than reduced from a solid wall deposit on the photographic image, and form the nucleus on which the visible image can be built up. The other action is that of which the paper offers an explanation, and is that which probably exists where the alkaline carbonate is used in lieu of ammonia in a solution of which silver bromide is apparently insoluble, and the image has to be built up from solid matter. The solution of the problem by Dr. Armstrong is that the action is an electrical action. That there is an electrical action produced goes without saying, for we know that the intensity of the photographic light and the comparison of the developing power of different developers acting on a silver salt have been measured by the current which has been produced. But the question arises, Which is the cause and which the effect, and are they not inseparable one from the other? In the symbolic reversible equation put forward by Dr. Armstrong, as that which may happen, he has—

and when the alkali is present, this is modified by replacing  $\text{H}_2\text{O}$  by  $\text{KOH}$ .

Now, it seems to me that this will scarcely hold as it stands, and is not quite analogous to the De la Rue cell, for in it we have a zinc and a silver plate opposed, and a solution of ammonium chloride, the silver chloride not in the main affecting the question, being a depolarizer. In Dr. Armstrong's equation we have a solid (latent image) opposed by a liquid containing not only what he assumes to answer to the zinc, but also what to the ammonium chloride, and there is no reason to think that such would act like a De la Rue cell. If we look at the bodies which really are opposed, we find that we have bromide of silver altered by light and bromide of silver. Now, this is much more analogous to the copper-zinc couple (which all those who are acquainted with chemical literature understand); the sub-bromide would take the place of the copper and the bromide of the zinc, and these must be what I may call at a different potential. If electrical action is to explain the phenomenon of development, it appears that we need not go further than this, and is in accordance with experiments which I made some years ago and published, from which I concluded that bromide of silver would not exist as such when in such contact as that in which the zinc and copper are in a zinc-copper couple, but that an interchange would take place immediately, and that we should have a production first of what I will call sub-bromide, and finally metallic silver. The couple would then be represented by silver bromide and metallic silver, and the difference in potential would be greater, and the action would be more energetic (which is what we know to be the case) until the electrolyte became inactive.

The electrolyte is the developing solution which is capable of absorbing oxygen, the water of solution being decomposed in the usual way, the hydrogen combining with the bromine. The solution of developer containing alkali is naturally in a better state for fulfilling the conditions of an electrolyte, and it may be partly for this reason that a solution of pyro by itself is incapable of developing a plate. [An interesting developer is made by pyro and sulphite of soda alone. These two alone will develop a plate after receiving prolonged application; but in this case the image appears to be developed by the solubility of the silver

salt in the developing solution.] I think that, omitting the bromide of potassium, the developing solution must be looked upon as a whole and (except in the case of solubility in an alkali) not as of separate components.

I do not agree with Dr. Armstrong as to the action of light being electrolytic. I think that the more simple explanation is given by considering it as a problem in molecular physics, and is more apt.

In reference to the darkened product of chloride of silver, I may interpose a remark. I have, like Mr. Baker, obtained a silver chloride *in vacuo*, thoroughly dried and free from moisture, and have had it for years in the sun without darkening, but some of the same chloride treated similarly, but in which at one end of the tube a drop of mercury had come over blackened, and calomel formed in the tube, and the blackening continued till the mercury had become converted into or been totally covered by this compound. In this case it may be presumed that the blackened chloride was not an oxy-chloride. The effect of oxygen on the latent image has been described by myself, and how ozone will destroy its developing power. Apparently this, on the electrical theory, is due to a want of difference in potential of the latent image and the bromide. The image may be again rendered developable by allowing a proper regulated stream of nascent hydrogen to pass over the surface.

The phenomena of reversal is one which I have long made a study—a study which I may say is incomplete—and there are phenomena connected with it which are curious to say the least. If, on a dimly-lighted white sheet I throw a spot of bright red light, and photograph the sheet on a plate which is not sensitive to the red, I find that instead of a uniform deposit to represent the image of the white sheet, the red spot comes out much less dense, showing that the red light renders the work done by the white light undevelopable. That is not what one would expect, for the same illumination of white light is all over the screen. If, instead of photographing this on a plate exposed to the air, it is photographed on a plate exposed *in vacuo*, or in a solution of nitrite of potassium, the reversing action apparently disappears. This phenomenon is really the same as that described by Claudet when he obtained a reversed image of a red sun, not due to over-exposure, however. Reversal then may be from several causes, only one of which I have noticed, but it appears that the others may be explained on the theory of oxydation. In experimenting on these points, it must not be forgotten that it is useless to use a gelatine plate which contains a substance which renders any deductions to be made from it doubtful.

It is worthy of remark that collodion dry plates, after exposure, keep but a short time under ordinary conditions, but, if kept away from oxygen, will keep very much longer. From these considerations it seems to me that we have to conclude that the image can scarcely be formed by an oxy salt, since these are difficult to develop. The explanation offered by Dr. Armstrong of course may be correct, but I think experiments of a crucial character may be devised to try if it is correct. As to recurrent reversal, I think there is not much known at present, but this I will say, that if the exposure be so prolonged that we get a suspicion of metallic silver, then the electrical theory, on the principle of couple zinc-couples, might account for it, for a difference in potential would again be established. Jansen, I believe, obtained this reversal on tannin plates.

## Table of Plate Speeds.

THE following table of the speed of various plates has been compiled by Mr. Alfred Watkins from actual tests in the camera, and is corrected to June, 1892, the developer used being pyro 2 gr., bromide 1 gr., ammonia 2 min., meta-bisulphite of potash 1 gr., water 1 oz. "These numbers must only be regarded as approximate and a guide to the first trial; for in the first place few makes are always issued at the same sensitiveness, and in the second place different workers vary in their method of development and in their idea of what a negative ought to be. . . . The numbers are all calculated for fully-exposed (not merely pretty) negatives, the developer used having a minimum of alkali. Many good workers,

especially those using stronger developers, find they give over-exposure, and therefore use numbers one-half greater, or even double, those suggested."

This table is calculated for use with Watkins' exposure meter, but is applicable to any other system of exposure.

## UNSOLICITED TESTIMONIAL.

2, ST. MARY'S ROAD, CANONBURY, N.,  
July 14th, 1892.

Messrs. MARION & Co.—Gentlemen,

I have been trying your three qualities of Plates—Ordinary, Rapid, and Instantaneous—on a variety of out-door subjects, in bright and dull weather, being guided as to exposure by the new Actinograph (Hurter & Driffeld's Patent), and “speed” marked upon the packages. As the result I find the system uniformly successful, for I have not lost a single plate.

Yours very truly,

JOHN SPILLER, F.C.S., F.I.C.

**MARION & CO., 22 & 23, Soho Square, London, W.**

## The Collodio Chloride Printing-Out Process.\*

By G. H. Moss.

THIS process is a very old one. It was first introduced by Wharton Simpson in 1864, but it has not been used much in England until recently. In America and on the Continent it has been extensively used for some time past, on account of the better results obtained.

One of the most important articles used is high temperature pyroxyline or gun cotton. The pyroxyline obtained at the ordinary photographic dealer's is perfectly useless for this purpose, being far too tough and horny. It is impossible to coat the paper without considerable trouble. It will also frill and blister in the toning and fixing bath. What is desired is a powdery cotton such as may be obtained at Rouch and Co.'s, Strand, who manufacture it especially for collodion emulsion processes.

To prepare the emulsion, first take 16 gr. of sodium chloride and 16 gr. tartaric acid; add 30 minims of hot water. When dissolved add 3 oz. of methylated alcohol; this should be purchased at a reliable shop, as many small dealers do not sell the pure article, but substitute methylated finish, which is useless for this purpose. In another bottle put 120 gr. silver nitrate and 60 minims hot water. I generally put the bottle on the kitchen hob to dissolve by heat. When the silver has all disappeared add methylated spirit 3 oz.

Now take a 20 oz. bottle and put in 90 gr. of gun cotton, pour the silver nitrate solution to this and shake well for a minute or two, then add 5 oz. of methylated sulphuric ether; shake up well until all is dissolved. It will then form a light greyish-white emulsion of silver nitrate in collodion. Up to this point the emulsion can be prepared in daylight.

The solution of chloride and tartaric acid is now added, a very little at a time, to the collodion. Directly a drop of chloride enters the collodion it will then turn milky. The bottle should be well shaken at each addition of the chloride. When all is added and well shaken, the emulsion must be put aside for about twelve hours to allow all the impurities to settle. It is then filtered through a piece of wadding.

The emulsion is now ready for coating the paper. The ordinary lithographic paper answers well; it is coated with a solution of arrowroot. Those who would prefer purchasing the paper ready for coating, I would recommend the support for the single transfer paper sold by the Autotype Co.; it is a paper coated with an insoluble gelatine.

I always coat my paper in a double frame, which holds it tight and prevents the emulsion from running over the edges. (The frame produced resembled a common drawing slate minus the glass, with a hole in the corner to pour any excess of emulsion off).

The coating is done in the same manner as in the wet plate process. The paper should be used as soon as possible. It will not keep more than about a week, unless it is floated on an acid bath like the commercial albumenised paper before coating; it will then keep as well as any silver paper in the market.

The printing should go on until the deep shadows are bronzed, as it loses a little more in fixing than albumen paper. It prints much quicker than albumen paper, especially in winter. Any toning bath may be used; in fact, it is treated exactly the same as the ordinary sensitised paper, and can be dried between blotting paper. No dust will adhere to it, as in gelatino-chloride paper. The fixing bath should not be stronger than 1 oz. hypo in 10 oz. water. Fixing is completed in about eight minutes, after which the prints should be washed in running water for an hour. This process is, I believe, as permanent as any silver process can be. There is no treacherous albumen to deal with, and yet there is the ease and simplicity of albumenised paper. Captain Abney states these prints should be permanent and possess a *rare* beauty. Anyone who tries this method of printing will very soon discover that they have a remarkable amount of detail compared with other silver paper, whether gelatino-chloride or albumenised. Opal glass can be coated and printed out, toned, etc., the same as paper.

The emulsion will keep a long time if kept in a well-corked bottle and in a dry, non-actinic light. I always use a red bottle, as it can then be handled in daylight without any trouble.

## One's Own Photograph.

By THE REV. EDWARD HUSBAND

(Incumbent of St. Michael's, Folkestone).

AMATEUR photographers are often asked by their friends, in common with other persons, for a photograph of themselves, and it is pleasant to their friends to let the photographs be those taken by the amateur photographers themselves. And there is also this advantage, that it enables the subjects to feel perfectly natural and at ease with no one in the studio to look on except themselves. I adopt a very easy and simple method, which I should like to describe to your readers, in the hope it may prove of some help to others under the same circumstances. All that is wanted is a head-rest in front of the background. Put yourself naturally into position, after having fastened a piece of string across the studio the height of your eyes from the ground. Then move forward till, standing in

the position you have chosen for the photograph, the string presses gently against your eye-lid. Then reach behind you, and pull the head-rest forward to its proper place, the string in front touching your eye-lid as directed, and the head-rest comfortably pressing against the back of your head. If you have any fear that the head-rest shows in front, rig up a looking-glass in front of you, and see if all is right. Then move quietly away, and hang a little piece of closely-printed paper over the string just in the place where your eyes would be. Go to your camera, focus the printed matter sharply; set your shutter for a time-exposure at the speed required, draw your slide (having removed the string), and stand just where you did before, your head gently pressing against the head-rest. Of course, attached to your shutter you have a long piece of tubing, with an extra large pneumatic ball. Hold the ball in your

\* Read before the South London Photographic Society.

hand in such a position that neither ball nor tubing will show in the negative. Then press the ball, and give the exposure required, and the deed, so far, will be done. I send you a photograph in platinotype which I took in this way last week of myself, on one of Edwards's instantaneous Isochromatic plates. The negative has not been retouched in any way, but is just as it came out of my developing dish, except that it has been dried and varnished, as I wish to let your readers see the result just as it was produced by my string and printed paper process, like the old lady before she went to the wig-maker and the manufacturer of false teeth. I ought to add that it is well to use a small stop, say  $f/32$ , and ensure sharpness under somewhat adverse circumstances. In this way anyone can become his own photographer.

## Holiday Resorts and Photographic Haunts.

### DORKING.

DORKING, situated in Surrey, twenty-five miles south of London, is a place which every photographer should visit. It can be reached by the London, Brighton, and South Coast Railway or the South Eastern, and is within an hour of London. The town is the centre of a very lovely district, in which many excursions can be made, both photographic and otherwise. A small stream—the Pip Brook, runs through the town, and forms two large mill, ponds, or rather one mill-pond in two sections, by the side of which there is a pleasant walk under the shade of some old willows. Passing along this path, which is entered over a bridge by a mill at the commencement of the town, the photographer makes a detour which brings him out by the parish church, a modern building in the perpendicular style erected in 1875, which can only be photographed with a wide-angle lens. From the church a narrow passage leads back into the High Street. Keeping to the right for some distance brings him to the junctions of South and West Streets with the High Street. Near this corner is the post-office, and by keeping down a turning beside it, he will come to an inn, the Old King's Head, which was formerly called the Marquis of Granby, and which Charles Dickens has rendered famous as the hostelry at which Samuel Weller used to put up. Returning to South Street, and keeping along the Guildford Road for some distance, he will come to a turning on the right which will take him to an old Elizabethan farmhouse, called Milton Court Mill. This is rather difficult to photograph, on account of its position. Across some fields is Pixholme Mill, where a plate may be exposed. Another path leads to Castle Mill, where another plate may be exposed. Then keep through Betchworth Park—some of the trees of which are very fine—towards Reigate, or along the road outside the park, and across Betchworth Bridge and up Box Hill, and down by the Burford Bridge Hotel, which should be photographed, and across the Mole by a picturesque bridge.

Another tour may be made by crossing the common to the south of the town known as Cotmandene, and through the Glory Woods to Holmwood.

E. T. H.

## Societies' Meetings.

**Belfast.**—On the 7th inst. the usual monthly meeting was held, Mr. T. B. Scott presiding. The prints in the monthly competition were on view, the awards having been made as follows:—First prize, J. A. Pollock, "Ess na Crub" Waterfall at Glenariffe; second place to J. McCleery for "A Rest at Noon," a study of sheep in Scarva Demesne; and third place to W. H. McCleery for "Easter Snow," at Glenariffe, Co. Antrim. Messrs. Houghton and Son, London, sent one of the new Shuttle hand-cameras for inspection of the members; the ingenious method by which the plates are changed and shutter set by the one movement should make it one of the most popular in the market.

**British Association.**—Mr. O. W. Jeffs presented the report of the Committee on Geological Photographs, which stated that the

number of photographs received and registered since the last meeting of the Association was 112, bringing the total contents of the collection to 700. The committee urged upon geologists the desirability of promptly assisting the scheme, in order that their work might be proceeded with as quickly as possible. A vote of thanks was passed to the committee.

**Dewsbury.**—Monthly meeting on the 11th inst. Owing to the technical school being closed for the vacation, the meeting was held in the Infirmary Board Room, at the invitation of the Secretary, Mr. C. J. Abbs. No special business being down for this evening, the members present indulged in a pleasant chat on various matters photographic. Sample packets of Paget Prize Plates were handed round, and a number of prints from negatives on the Paget plates were shown by the Secretary, G. Kilburn. The prints shown were made on the new paper by the Eastman Photographic Company, also a number of prints by other members on the same make of paper. Several members stated their experience in working both the Ilford and Eastman papers. It was decided to have an outing to Bolton Woods on Saturday, August 27th.

**Fairfield Camera Club.**—The eighth ordinary meeting was held on 9th inst., the President (Mr. J. L. Mackrell) in the chair. After the election of new members he proceeded to explain and exhibit Mr. Paul Lange's new hand-camera. Owing to the absence of the lecturer for the evening, Mr. Mackrell gave a practical demonstration on "The Reduction of the Density of Negatives Locally and Otherwise." This he dealt with in his masterly manner, it proving a most interesting and instructive subject. Some fine prints in the new cold-bath platinotype process, the work of Mr. Stockdale, were exhibited and greatly admired.

**Hackney.**—Meeting held on 9th inst., Mr. Arthur Barker in the chair. The Hon. Secretary distributed samples of the Paget plates and Ilford printing-out paper. A discussion ensued on the latter. Mr. Hensler said he noticed a difference in the colour, which was sometimes red and sometimes violet. He preferred the latter. Mr. Nunn differed. Mr. Beckett said some negatives were more suitable for one colour than another—blue paper lost the most in bath. Mr. Dean handed round a frilled plate. Mr. Dando said it was very much forced. Mr. Hudson showed some cheap sheaths made by Chipper. Mr. Nunn showed some examples of work on the Paget Phoenix plates, which he had been very successful with. Mr. Reynolds also reported favourably of the same plates. Mr. Poulson asked the chairman's opinion of the Eastman gelatino-chloride paper. The Chairman said he had used a quantity, and was very pleased with results. The Assistant-Secretary informed the members that the excursion next Saturday, 13th inst., would be to Theydon Bois. Meet at that station at 2.40. Mr. Roofe was nominated. Mr. W. G. Roberts, of Leytonstone, then showed his hand-camera, which could be used on a stand and focussed as an ordinary camera. Although being of a magazine kind, changing could be done in daylight by carrying extra small magazine. Mr. Dando then proceeded to read an excellent paper on "Stereoscopic Photography." He attributed the discovery to Sir Chas. Wheatley. A half-plate camera had been used by Mr. Dando for his work, and he said he had found it an advantage, as extra height was allowed. Two different pictures could be taken, if desired. Another advantage in the size mentioned was that half-plates could always be obtained. He preferred the shutter just before the plate, and lenses of from 5 to 7 in. foci. One of the great difficulties was to get them accurately paired. He did not like the iris diaphragms. Sometimes apertures were not equal. Give plenty of exposure, and develop rather thinly, and get plenty of detail. Mr. Hensler asked how to tell when accurately paired. Mr. Dando said: Take lens out, pass thin piece of wood through one of the stops so that the wood is marked all round, then repeat on the other. Further discussion was postponed until next meeting.

**Harlesden and Willesden.**—A meeting was held on the 9th inst. Mr. Clapton gave an interesting lecture upon the subject of lenses. The Secretary, Mr. Woodbury, of 23, Fairlight Avenue, Harlesden, is particularly desirous that the existence of the Society be made known to the numerous amateur photographers residing in this and neighbouring districts, and will be happy to give all information to those likely to join.

**Hove (Camera Club).**—On the 9th inst. the Hon. Secretary (J. Williamson), gave a demonstration on the manipulation of gelatino-chloride paper. Some prints were toned in the sulpho-cyanide bath, some in the borax bath, and some in a new toning and fixing bath recommended by the Eastman Company. Those toned in the sulpho-cyanide baths were fairly satisfactory, but it was found that in order to secure an even tone the process had to be continued rather beyond the tone desired. Unevenness of toning appeared to be the general experience of the members present in using this bath. It was suggested that this might be due to acidity of the bath, which further experiments were required to prove. The borax bath which had been prepared the previous evening absolutely refused to tone until some more gold had been added; toning

then took place very satisfactorily. The combined bath, in two solutions, mixed at the time of using, toned quickly and evenly, giving a rich warm purple, longer toning giving a darker colour. Doubts were expressed as to complete fixation of the prints, but the demonstrator passed round a print which after being in the bath for three minutes and exposed to two days sunlight showed no degradation. Mr. Williamson said that this appeared to him such an extraordinary combination—containing hypo, alum, and the sulphate of potash and soda in one solution, and chloride of gold and sugar of lead in the other—that he hesitated to use it. However, a representative of Eastman's firm had shown him some remarkably fine specimens which had stood some severe tests, and after giving it a fair trial he had no hesitation in recommending its use. Care must be taken not to put the prints into ordinary hypo solution after this bath, or a splendid example of sulphur toning would result. If further fixation were considered necessary it should be put into the No. 1 solution (without gold) for a short time. One print each of Ilford P.O.P. and Eastman's gelatino-chloride were toned in each bath, and the tones obtained in each case were identical, although the Ilford prints were purple and the Eastman brownish-red. Washing by changing the prints from one dish to another of fresh water was recommended in preference to leaving the prints in running water, and by squeegeeing the prints between each change elimination of hypo was considerably hastened. The process of finishing, enamel or matt, was then shown. Backing with waterproof paper was not approved of. He experienced no difficulty in mounting enamelled prints. Two were shown which had been coated on the back with dextrine paste before removing from the glass; these were damped with a soft sponge, and adhered perfectly to the mounts without damaging the surface, a piece of waxed paper being used to rub it down with. A number of specimen prints on Ilford printing-out paper and Eastman's paper were passed round for inspection, and some samples of printing-out paper sent by the Britannia Works Co. were distributed. Sample packets of the Paget Prize plates had also been distributed. A Cantelever enlarging apparatus was shown by the Secretary.

**Liverpool (Camera Club).**—The usual meeting was held on the 10th inst., the President (Dr. Webb), occupying the chair. The minutes of the previous meeting having been read and confirmed, Mr. W. A. Brown reported on the club excursion to Rabymer and District. Owing to the thin attendance of members (on account of the holiday season) it was resolved that the results of the Paget Prize Plate exposures be left over until another meeting. The next meeting will be held on Wednesday, 24th inst., when a paper on "Optics for Amateurs," will be given by Mr. H. Handley.

**Nottingham Mechanics' Institution Camera Club.**—The meeting of this club, which was well attended, was held on the 9th inst. The minutes of the previous meeting were read and confirmed. A unanimous vote of thanks was passed to Lord Middleton for his kindness in permitting the members to visit Wollaton Hall, to Mr. W. Wright for his courtesy in making the necessary arrangements in connection with the visit, and to Mr. Harris, who acted as cicerone on each occasion. The Secretary (Mr. J. T. Radford) reported that the Committee of the Club had decided to offer three prizes for competition amongst the members for work done on the excursions up to the end of the year. A cordial vote of thanks was passed to Mr. Flowerdew for his extensive exhibition of photographic apparatus and appliances, and his explanation of them to the members at the last meeting, after which there was an exhibition of stereoscopic slides, etc., kindly lent by Mr. H. A. Jackson, and also an exhibition of members' work in connection with the excursions to Wollaton Hall, etc., which were inspected with great interest by the members present. It was announced that the book on "Photography" by A. Brothers, F.R.A.S., had been ordered to be bought, and it could be seen by the club members at the library on application at the librarian's counter. Excursions are to be made this month to King's Mills and Cromford and Matlock.

**Richmond.**—On the 12th inst., the President in the chair, the Hon. Secretary distributed sample packets of plates sent by the Paget Company, and printing-out paper sent by the Britannia Company. He then said that he had some difficulty in stripping gelatino-chloride prints that had been squeegeed on glass: would xylonite slabs answer better? Mr. Cembrano (the President) had never had a failure in squeegeeing. When using the Ilford paper, he commended for this paper a combined toning and fixing bath. The xylonite slabs mentioned would be a capital substitute for the focussing screen, provided they were made sufficiently rigid and transparent. Mr. Davis recommended rubbing a little powdered pumice stone to get rid of the small bright specks on matt-surface prints. In opening the discussion on "Developing Under-exposures," Mr. Davis said he employed the old method of first soaking the plate in a weak solution of the accelerator, pouring this off and applying the usual developer; this system answered well when the plate was known to be under-exposed, but there was danger

of spoiling the negative if the exposure happened to be a full one. Mr. Ennis preferred diluting the developer with four times its bulk of water, then when the image was well out, he would use the fresh developer containing little bromide. Mr. Hunter would begin with a developer containing less pyro, ammonia, and bromide, and when all the possible detail was out, he would strengthen it by adding plenty of pyro and more ammonia. Mr. Cembrano thought that if the plate was really underexposed no good could be done with it. It was in under-exposure that defects in the manufacture of the plate would become very apparent. He believed, that in practice there was no real advantage of any one developing agent over another. When having a good subject, the best and safest plan would be to expose two or more plates on it. Mr. Ford had not succeeded in real cases of under-exposure, not even after developing for two hours. To gauge correctly the exposure for subjects under trees was a difficult matter. Mr. Ennis found the soda developer recommended by the President to work well for hand-camera exposures. It was made as follows: Sulpho-pyrogallol, 10 per cent., 20 min.; washing soda, 10 per cent., 240 min.; bromide potassium, 10 per cent., 2 min. Make up with sulphite of soda 10 per cent. to 1 oz., instead of plain water. Mr. Davis found it was essential to use bromide with the pyro-potash soda developer. Mr. Ennis asked for the best way of mounting glazed gelatino-chloride prints. Mr. Davis said Houghton's Excelsior mountant was good. Mr. Ford added that india-rubber solution answered, but it caused the prints to fade. Mr. Ennis had had a similar experience with this mountant when mounting prints on albumenised paper.

**Sheffield.**—The ordinary monthly meeting was held on the 9th inst., Mr. B. J. Taylor in the chair, when after the usual routine business of the meeting, the final arrangements were made for the week-end excursion to Whitby, which bids fair to be a great success. The Secretary passed round among the members sample packets of the Paget Prize Plates for members to report thereon at the next meeting. Several members also gave in their report in reference to Eastman's printing-out paper, which was considered very satisfactory. It was also arranged to send the annual competition pictures to London for judgment.

**Spen Valley.**—The monthly meeting of the above Society was held on the 9th inst., Dr. Farrow, President, in the chair. The adjudication in the monthly competition, the subject of which was "Caught," was proceeded with, the prize being awarded to Mr. J. Burnhill for a picture of a rat in a trap. This was also the time appointed to judge the prints sent in to the Sutherland competition, and as it was the first competition of the kind in which any prize of value had been competed for, there was considerable interest taken in it. The subject was to be Lower Blamp Farm, from a given aspect. There were ten exhibits, all of which were very creditable to the competitors, the prize being awarded to Mr. H. Jackson. A discussion then took place as to the best means of judging photographs at future exhibitions.

**Stockton.**—The usual monthly meeting was held on the 9th inst., Mr. H. Macdonnell presiding, at which Mr. Ellam, the Hon. Sec., gave a practical demonstration in the making and varnishing of window transparencies, from negatives brought by the members. Success crowned the demonstrator's efforts, and delighted a large attendance of members. Sample packets of plates, kindly sent by the Paget Prize Plate Company, were afterwards distributed amongst those present.

**Tyneside.**—A general meeting was held on the 9th inst., when Houghton's Shuttle hand-camera was exhibited, the Secretary describing and working the ingenious instrument. The Paget Company sent samples of plates, which were delivered to the members. Ilford "Scraps" were also delivered.

**Warrington.**—The usual meeting was held on the 9th inst., a large number of members being present. In the absence of the President, Mr. T. J. Down, Mr. H. N. Houghton presided. A practical demonstration on the working of the "Ilford Printing-Out Paper" was given by Mr. G. H. Brown, Penketh, commencing first by giving its history, the manufacture, the advantages over other silver papers, rules to be observed, printing, toning, fixing, defects and remedies. Prints were passed round showing the various colours obtained through injudicious handling, such as stained fingers, dirty dishes, etc. Two prints were next washed, toned and dried on glass with successful results. Mr. Lawson, of Newton-le-Willows, another member, introduced to the meeting his patent limelight saturator as shown before the London Lantern Society. Judging from the ingenious make and its simple action, it bids well for success, especially to those lanternists who are in the habit of exhibiting in the country, where hydrogen gas cannot be obtained, the saturator doing away with this gas altogether. Mr. Lawson is making a new one on the same lines that can be made to fit into any lantern.

**Wolverhampton.**—The monthly meeting was held on the 9th inst., Mr. H. Holcroft (President) in the chair. Mr. J. Gale, one of the Society's most prominent members, who was announced to give a paper on "Ammonio-Nitrate of Silver Printing on Rough Drawing

Paper," tendered an apology for being unprepared to give the paper in the explicit form upon which he had based his promise, preferring rather to postpone the subject for a week or two pending scientific experiments. With a view of relieving the tedium of suspense, therefore, Mr. W. Radcliffe exhibited a "home-spun" camera and stand, and a shutter, which he stated had actually cost him but a single penny. The President expostulated upon the many and varied attempts to obtain genuine and natural cloud results, and as Mr. Holcroft is a gentleman of wide experience, his address was listened to with much earnestness. The Honorary Secretary (Mr. J. W. Evans) announced that he had been supplied with a free sample parcel of dry plates by the Paget Prize Plate Company, of Watford, for distribution amongst the members, who expressed their willingness to see what they were like. The latter portion of the proceedings was devoted to arranging a half-day "brake" excursion, which, after a little diversified controversy, was arranged to take place on Saturday, the 27th inst., Worfield being the rendezvous.

**York.**—The first meeting in the new room, Victoria Hall, was held on the 9th inst. The members had been invited to bring their recent work for inspection, and as a good response was made to the request, a very pleasant and profitable evening was spent in examining the various specimens exhibited. The President (Mr. F. Vincent) showed prints from half-plate negatives enlarged from lantern-slides by means of a Griffiths' fixed-focus enlarging or reducing camera. Mr. G. Pawson had a large series of whole-plate negatives of black and white reproductions, and as they included examples of nearly all the known methods of development and intensification, a comparison of the same was very instructive. A pyro-ammonia developer, and mercurial intensification with ammonia, was considered to give the most successful results, although one plate intensified with uranium was very good. The difficulty in this branch of photography is to obtain sufficient density, and at the same time retain the lines of the print as absolutely clear glass. Mr. Dickinson had some prints on the Ilford printing-out paper which showed in a very comprehensive manner the range of tones obtainable by means of this process. Mr. Hick showed two negatives of the interior of a church—one on a well-known make of dry-plate, in which, notwithstanding the usual precaution of "backing" the plate had been taken, halation was very strongly marked, while the other negative taken on the Sandell plate, with ten minutes longer exposure, was totally free from the slightest sign of the defect, and a comparison of the two afforded a striking example of the value of the new plate. Mr. Hick also showed some excellent examples of portrait work printed on the Ilford printing-out paper. Mr. Redpath showed negatives of Jesmond Dene and Goathland, and Mr. Tittensor a large collection of stereoscopic negatives.

"The Bohemian" caravan has arrived in London, and the Duke of Newcastle and Mr. Gambier Bolton have returned with a number of very interesting negatives, and a long list of most amusing adventures. We hear that the Queen has presented Mr. Gambier Bolton with a handsome white Scotch collie from her private kennels at Frogmore. An account of these, illustrated by Mr. Gambier Bolton, appeared in the pages of our contemporary, *The Stock-Keeper*, last spring.

**Professor Vernon-Boys on Electric Spark Photographs.**—The second of a series of evening lectures and one specially for artisans, was delivered in Edinburgh on 6th inst. by Professor C. Vernon-Boys, South Kensington, London. The subject was "Electric Spark Photographs, or Photography of Flying Bullets, etc., by the light of the Electric Spark." Professor Vernon-Boys said the subject he took up that night was that of the mode of investigation pursued when that subject of investigation—whatever it might be—was moving at so great a speed as not to admit of its being examined in the ordinary way. In dealing with instantaneous photography he was dealing purely with the mechanical and not the photographic subject. Instantaneous meant something that lasted so short a time that to their senses it lasted no time at all. The Professor then, by means of a large carboard clock face revolving at a high speed showed that by the magnesium flash the figures could not be distinguished, while an electric spark lit up the dial plate, and distinctly brought out the figures. To further illustrate the photographing of articles in motion a view was thrown on the screen of an express train in motion. The next view was that of a soap bubble in the act of bursting, and after explaining that by the electric spark articles moving at the rate of 10,000 miles an hour could be photographed, the Professor stated that by the introduction of a revolving mirror, a speed of 180,000 miles an hour could be coped with. The mirror—one being shown working—made 1,024 turns every second, worked by electricity, which was equal to about one hundred and fifty times as fast as a rifle bullet travelled. The whole photographic power of the spark was over in a time equal to the ten or eleven millionth part of a second. Proceeding to the subject of photographing rifle bullets in motion, he said that so far as he knew the first photograph was taken in Austria by Professor March, who caused the bullet to travel between two wires joining an electric circuit, and thus producing the electric spark. The Professor next explained in what his method differed from that of the Austrian Professor, and demonstrated the actual working of the experiment, the bullet being shot, a few yards distant, into a box of bran, the photograph being taken in its transit into the box. An ordinary camera was used. Views were next given of many photographs taken by the Professor, commencing with a bullet fired by a pistol, next of a Martini-Henry bullet, and last that of one from a magazine rifle. Special attention was drawn to the clearly-defined air waves shown on the photographs—the angles of these waves being more acute the greater the speed at which the bullets travelled. The magazine rifle bullet, travelling at a speed of 2,000 feet a second, had very acute air-waves, while in the trail of the bullet was seen the air disturbance like the turmoil of water in the wake of a steamer. Up to a certain rate of speed the air waves were horizontal, but beyond that speed they gradually became vertical. A view was also displayed of a choke ball after being fired with No. 8 shot, showing that the spread of the shot was only three or four times the diameter of the barrel of the gun at about three yards from the muzzle. The lecturer concluded with views of a bullet going through glass.

**Improved Photometers.**—Photometers, involving the employment of materials such as selenium, that are sensitive in respect of their electric conductivity to the action of light, have not, up to the present, proved very successful, owing mainly to spontaneous alterations in the materials themselves. To overcome this difficulty, Mr. E. Thomas, of 18, Sisters-avenue, Wandsworth, S.W., ingeniously proposes that the photo-sensitive arrangement should be subjected alternately, in rapid succession, to the light to be tested and to a standard light. The mean effect while facing the one light may then be compared with that produced while facing the other. One method of carrying out the invention with a selenium cell consists in mounting this upon an arbour capable of being rapidly rotated. While facing one light, contact is made automatically, so that a current flows through a galvanometer for a small fraction of a rotation. And when, in the course of its movement, the cell faces towards the other light, contact is again made for an equal fraction of the rotation, but the current now flows through the galvanometer in the opposite direction. This is repeated many times a second; and, of course, provided that the cell is equally illuminated by the two lights, the galvanometer will not be affected. Instead of rotating the cell itself, a mirror or mirrors, or other optical device, may be rotated in such a manner as to subject the cell alternately to the two sources of radiation, or suitable optical arrangements may be made for cutting off the radiation from the two sources alternately by means of a moving screen.—*Optician*.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by **TUESDAY MORNING'S POST**.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

### QUERIES.

5788. **Enamelling.**—Will any brother amateur, or professional, kindly describe the art of enamelling who has had some experience therein, and detail the constituent parts of ingredients used? By doing so he will oblige a fellow worker.—THOS. CLARK.

5789. **Ilford P.O.P.**—Can anyone tell me why the Ilford P.O.P. should turn yellow in toning? Sometimes one print will turn yellow and another from the same negative will not do so. I have to take the prints out very quickly; the longer they are in the bath the yellower they become, and still worse in the hypo. I like a warm sepia tint, but do not wish for bright yellow. I was told that I must have got some hypo in the toning bath, but I do not think I have any. I use a sulphocyanide bath, according to the directions given with the paper. My negatives are not varnished; would that affect the paper?—MAN-FIELD.

5790. **Instanto. Shutter.**—Will one of your readers kindly state the quickest and also the slowest speed of the shutter of Lancaster's Instanto camera?—WILLIE.

5791. **Dark-Room Wanted.**—Can any reader inform me of the address of a dark-room at Strathpeffer, Scotland?—TORRIDON.

5792. **N. Ireland.**—Will someone kindly oblige by giving information about North Ireland, viz., Portrush and the Giant's Causeway? Would Portrush be the best place to stay at, and are the hotel charges moderate? Any other information will greatly oblige.—CANTABRIGIA.

5793. **Bromide Paper.**—In developing with the Ilford (or any other) hydroquinone formula, is it necessary or desirable to use an acid clearing bath; and if so, why?—DOZEY G.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

### QUERIES UNANSWERED.

July 15th.—No. 5756.

„ 22nd.—Nos. 5763, 5768.

„ 29th.—Nos. 5777, 5778.

Aug. 5th.—Nos. 5779, 5780, 5781, 5785, 5786.

### ANSWERS.

5766. **Sat. Sol. Hypo.**—The strength of sat. sol. hypo varies according to temperature, but at 62 deg. Fahr. the following results of careful experiments may be relied on for practical photographic purposes:—1 oz. of hypo crystals is contained in 9.55 fl. drms. of sat. sol. 1 oz. fluid of sat. sol. contains 874 gr. of crystals. 1 oz. of water will dissolve 736 gr. of crystals, the measure of the solution being 15½ drms. It is a good plan to keep an excess of hypo in soak in large jug, stirring well, and giving plenty of time for perfect saturation, and occasionally filtering a portion into a stock bottle. A solution of any given strength can then be made in a moment.—J. M. COATES.

5772. **Powell's Compressed Gold Baths.**—Use these with less water; say the contents of a tube dissolved in a quarter, instead of half a pint of water, and procure the Ilford printing-out paper as fresh as possible; you will then have no difficulty in producing deep tones.—J. VEALE WILLIAMS.

5787. **Yarmouth and Lowestoft.**—I do not think "Trix" will have much difficulty in finding plenty of pretty little bits near Lowestoft and district. To commence with, Lowestoft and Kirkley churches are well worth an exposure, one or two nice views of the harbour and pier may also be found, but most of the pretty bits are found outside Lowestoft. The following places will afford many nice pictures for a half-

plate camera:—Entrance to Belle Vue Park and Jubilee Bridge, and High Light, Corton, Carlton Colville, The Denes, Pakefield, Kessingland, Southwold, Oulton Broad, St. Olaves, and Fritton Decoy, Burgh, Staithes, Brundall (for Surlingham Broad and Ferry), Wroxham Broad and Horning Ferry, Hickling Broad. Norwich is also worthy of a visit with the camera, the most interesting views being the cathedral, castle, and river. At Yarmouth the following are to be noted:—Church, market, and the suburb of Gorleston. Several of the above places are within walking distance of Lowestoft, and the remainder may be reached by short railway journeys or drives. And, lastly, if "Trix" is fond of the water and rowing, an innumerable variety of pretty bits may be obtained on all the rivers and waters near Lowestoft and Yarmouth.—MAC.

5787. **Yarmouth and Lowestoft.**—There are so many things worth doing here that to enumerate them would take far too much space. I can assure "Trix" he would find ample employment for a week or ten days, or even more, at Yarmouth. There are the docks, steamers, town hall, beach, fishing and pleasure boats, old church, the Rows, etc. At Lowestoft, the North Park, sands, fish markets, etc. At Beccles, the quaint old detached tower and fine old church, avenue, market place, River Waveney, etc. I am staying here for a few days, and shall be pleased to give "Trix" any information.—Address with Editor.—DOZEY G.

### EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us before **TUESDAY MORNING'S POST** if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

G. L. WOOD.—Add bicarbonate of soda to make bath alkaline. If you use the combined baths as recommended by the Eastman Company, and do not use them too long, you need have no fear as to the permanency of the prints. Although distilled water is preferable, it is not absolutely essential and would not make much difference.

R. DUDLEY TUCKER.—Direct enlargements are barred from competition.

S. ROUT.—The peculiar positive-like appearance of your negative is due to the silver being deposited in an allotropic white condition. It really need not trouble you, as it is quite harmless.

F. A.—The description of your stained negative reads as though only half of it had been washed, and the stained half left in contact with the air. We are afraid there is nothing to be done for it, but if you will send us up the negative we will see.

POPE GREGORY.—Bausch and Lomb's new diaphragm shutter is the nearest approach to what you want; Whittingham and Co., Charterhouse Square, are agents.

J. T. TITMAN.—You cannot do better than get the lens you name; they are about the most satisfactory in the market.

TRIX.—(1) We cannot state whether the R. R. would fit in your dangle, anyhow it would not be a difficult matter to adapt it. (2) The difference of exposure with two different lenses depends solely upon their ratio aperture, that is to say on the ratio of the diameter of the opening of the lenses. In the "Merveilleux" this is about f/11, or 1-11th of the equivalent focus of the lens: in an R. R. lens, this is usually f/8, or one-eighth of the focus, and the exposures are as 8:11 squared, or as 64:132, or practically the R. R. lens would require about half the exposure with Merveilleux. We are afraid almost to give you any guide to the exposure in a cathedral, but we should say that you will not err much if you give about half an hour, especially with a well-lighted place. (3) We prefer prints sent in to Holidays with Camera Competition on separate mounts, and they may be anything taken during the holidays, except pure portraiture of figure studies. (4) Halving the water is doubling the strength of the bath, consequently if 8 oz. is too little for your dish use 16 oz., only add 2 gr. of gold to it.

WM. RUSSELL.—We never undertake to buy or sell for our readers; the only thing we will do is to report on apparatus if desired, for which we charge 2s. 6d.

A. FLETCHER.—We would rather advise you to use out films in your dark slides. The printing operations are exactly the same as for plates, and if you will write in about a fortnight's time, enclosing stamped addressed envelope, we will write you privately and send you some specimens of work done with films by us.

G. H.—So far as we can trace, the only mention of stannous chloride as a developer, except Hunt, is a note by Eder, who states that alkaline stannous chloride solution acts very faintly as a developer, and that its power is very inferior in this respect to pyro or even ferrous oxalate.

A. WEBSTER.—The complaints we receive on the subject you name are very general, so much so that next month we hope to be able to institute a few experiments to see what can be done to remedy it. Our

experience so far leads us to say, considerably overprint and use the combined bath.

INQUIRITIVE (Bone).—(1) In all hydroquinone developer temperature plays a far more important part than with other agents. The temperature of the developer should be about 70 deg. F. If frilling is to be feared you should use the alum and hypo fixing bath of Lainer, which effectually checks it. (2) The want of sharpness you deplore in our reproductions is undoubtedly due to the process, and not always to the print. On the other hand, printing on rough-surface papers is gaining ground rapidly in England, and this leads to suppression of what is called "obtrusive detail." There is a tendency of "artistic research," if you like to call it so, for general haziness or "fuzziness." (3) Undoubtedly the single. Next to the portrait lens proper, the best lens for portraiture is the single lens, but it should work at a larger aperture than f/7 or f/8, then you get beautifully soft results. (4) All our competitions are open to all our readers, provided they are amateurs, no matter where they live. Write and ask us for entry forms, and we will gladly send you them on. A. The figures are hardly necessary, and do not add to the artistic effect. B. Extremely inartistic. It is doubtless a very difficult subject to treat, but the straight line of the bridge, the blank foreground and blander sky are terribly distressing. C. Again of poor interest, the blank white patch of the Kouba is too glaringly white, and the right hand of the print is not required. D. Here you have about two inches too much foreground; the road is utterly without interest. E. Might well serve as a specimen of hand-camera work, only there is too evident posing "to be took" about the boys, and, although probably truthful, your blank skies would be improved by clouds. In technical work your prints are fully up to our standard, but we are afraid they are below as regards artistic qualities. The prints shall go in our specimen album. By all means try in our competitions.

ISO.—Your name shall be entered in our list. There are some mistakes, but we hope not many. A. 1 and 2 are up to standard, but what a pity to have spoilt 2 by the utterly incongruous figure! We should actually be tempted to cut the print in half, so as to cut the figure right out. B. No, the "Optimus" Competition would not disqualify you from ours. C. Certainly, if you improve a print so much there is no objection to your re-entering it. D. This is a very difficult question to answer; you do not say whether you are going to photograph pigments or natural objects, and there are so many different greens and yellows. Will you write more fully, and we will try and answer you more satisfactorily.

QUIZ.—We have a paper in type on "The Harmonising of Harsh Negatives," read before one of our London societies, which will probably give you all the information you desire. However, the following is Eder's method, and one we have used for some time with very good results. Soak the plate in water till the film is soft, then immerse in

Hydrochloric acid, pure	..	..	1 part
Alum	..	..	10 parts
Bichromate of potash	..	..	5 "
Water	..	..	100 "

till the image is bleached quite white, through the film, then wash thoroughly, say for half an hour in running water, and then redevelop with a ferrous oxalate developer, with bromide added. As soon as the thin portions have developed thoroughly, and before the dense portions have become black on looking through the back, wash and fix. There will be a much more harmonious result. The alternative method is to paint the back of the negative with red or yellow matt varnish, and scrape it away from all parts, except those which you wish to keep back in printing. The marks on your negative to which the paper stuck are "silver stains," caused by absorption of the free nitrate of silver by the damp gelatine, and it is almost a hopeless task to try and remove them. The remedies suggested, which are not without danger of removing the image entirely, are, first, a weak solution of cyanide of potassium, or secondly, ferrid-cyanide of potassium, and sulphocyanide of potassium; unless it is a valuable negative, our advice is, throw it away. We shall always be glad to help you to the best of our ability.

NEWS.—Pyroxyl is, according to its method of preparation, a mixture of dinitro, trinitro, tetranitro, pentanitro, or hexanitro cellulose, and is made by acting on cotton wool with a mixture of nitric and sulphuric acids, or sulphuric acid and nitrate of potash, washing and drying. The best pyroxyl is either a mixture of tetra and trinitro cellulose or tetranitro cellulose only. Fallowfield or Adams, Charing Cross Road, or Mawson and Swan, 33, Bobo Square, would supply you, and the price is about 1s. 4d. per oz.

J. M. COATES.—Many thanks for answer. Entry form sent on.

W. G. ROBERTS.—Letter duly received, and contents noted.

ROSE.—The print would be better if a little more deeply printed. It is also spoilt by the too evident posing of the figures.

CONSTANT READER.—(1) It would be advisable for you to write to the Editor of the paper named, and ask his permission to utilise his cuts as lantern slides and do the same with the publishers of book and photographs; this would get you out of any possible

trouble. (2) Wood's washer is very satisfactory in action. (3) Do you want a hand-camera for plates, films, magazine, or dark slides?

M. EGERTON.—Thanks for correction.

GEO. H. JAMES.—There is a book by Blake on the subject, the title and publisher of which we will try and find out for you.

STANLEY BROOK.—The negatives may be used for prints in any competition.

G. EMERY.—You will find on pages 12 and 23, full information on the toning of gelatino-chloride prints. Use the bath recommended on p. 23, which, if not used too long, will not reduce the permanency of your prints.

D. S. WHITELAW.—We have used the solution named with successful results ever since its introduction, therefore the statements are not true.

A. J. D.—Letter by post.

EMIGRANT.—Provided the apparatus, etc., is for your own personal use, you would not be charged.

F. G. BENSON.—Apply early, and then you will only have to pay carriage one way, as the slides will reach you on their rounds.

EMIGRANT-Pocock and Co., 7, Short Market Street; Heynes, Matthew and Co., Adderley Street; Lennon and Co., all of Cape Town, stock plates, chemicals, etc. In most large towns, too, you will find a photographic dealer.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence. Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the AMATEUR PHOTOGRAPHER, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques or Postal Orders, made payable to Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 5d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the EDITOR, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C., who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

**Cameras, etc.**—First-class half-plate camera, three double slides, bargain.—Maltby, 172, Blue Bell Hill, Nottingham.

Lancaster's 50s. quarter-plate camera and solid leather case, 30s.—61, Newman Street, W.

Will exchange my half-plate Cleveland, as new, for good hand-camera.—Field, 195, Grundy Street, Poplar, E.

7½ by 5 Ross camera, five double backs, all movements and improvements, practically new, cost 210s., price 105s., sacrifice.—Roberts, 77, Benwell Road, Highbury, London.

**Cameras, Lenses, etc.**—Optimus detective camera, rapid rectilinear lens, cost £6 6s., take £3 3s., or exchange stand camera.—Craven, Fitcham, Lynn.

Dallmeyer 6 by 5 R.R. lens, fitted with Newman's shutter, cost £7, sell £4; Watson's cabinet lens, new, cost 60s., sell 40s.; Lancaster's half W.A. rectigraph, cost 42s., sell 20s.; whole-plate Wray landscape, cost £3, sell £2; whole-plate finest quality square bellows camera, every movement, three double slides, cost £10, sell £6.—Paribby, Cradock Street, Swansea.

Half-plate copying or portrait camera and slide, 12s. 6d.; quarter-plate rack portrait lens, 10s. 6d.; four inch condenser, 10s.; large, powerful ruby lamp, 7s. 6d.—M. Newhouse, 90, Victoria Terrace, Lancaster.

**Hand-Cameras, etc.**—Cytex hand-camera, leather covered, carries 12 quarter-plates, weight 3½ lb., 50s.—Dr. Clark, 57, Addiscombe Road, Surrey.

For sale, No. 3 Kodak Junior, case, complete, 20 unexposed films, new this season, approval, deposit, £6.—E. Phillips, Bridge Street, Leatherhead.

Fallowfield's Facile hand-camera, quarter-plate R.R. lens, waterproof case, 75s.—Kerdell, 1, Hanover Park, Peckham.

King's twin lens focussing hand-camera for 12 quarter-plates, quickly changed, by Lever, three finders, one full size of plate, fitted Adams' famous

Ideal R.R. lens and Mignon shutter, always set, time and instantaneous, pneumatic release, covered real morocco leather, quite new, never used, cost £6, price £5.—No. 328, office of this paper, 1, Creed Lane, E.C.

Rouch's quarter-plate hand-camera, little used, perfect, £3.—Shelton, 5, Wellington Terrace, Whitby.

Kodak No. 3 Regular, perfect condition, with film for 30 exposures, price £5 5s.—Lister, Tanfie d Chambers, Bradford.

Beck's quarter-plate hand-camera; what offers cash?—H., 21, Kidbrook Park Road, Blackheath.

Presto camera, two extra slides, developing and printing accessories, bargain, 10s. 6d.—Strachan, 1, Claremont Road, Surbiton, S.W.

**Lenses, etc.**—9 by 7 R.R., aluminium mount, iris, London made, weight 7 oz., 11 in. focus, splendid instrument, as new; may be seen in the City; list price £7 10s., for 80s.; rare chance.—Apply, G. 2; Crofton Terrace, Kingstown.

Underwood's LL, 5 by 4, new, with instantaneous shutter, iris stops, 7/11, 1892 pattern, 15s.—Souhami, 372, Old Street, London, E.C.

Instantograph lens, half-plate, quite new, good definition, bargain, 16s. 6d.—J. Titman, Alford, Lincolnshire.

Back's 7 in. wide-angle rectilinear lens, in splendid condition, only used a few times, cost £5 10s. 6d., price 4 guineas; approval, deposit.—Hatfield, 2A, Oriental Street, Poplar, London.

**Sets.**—Full-plate camera on sale, complete outfit first class, nearly new. Would take good quarter-plate as part exchange.—A. R. Foster, Thornbury, Bradford.

Lancaster's 1891 half instantograph, lens, shutter, slide, tripod, three metal slides, case, finder, lamp, dishes, printing frames, etc., £4.—F. Rodwell, Blenheim Terrace, N.W.

Quarter-plate Stereoscopic camera by Horn and Thornthwaite, London, two lenses, two dark slides, tripod, chemicals, etc., complete. What offers?—No. 323, office of this paper, 1, Creed Lane, E.C.

Quarter-plate mahogany camera, rapid rectilinear lens, folding tripod, drop shutter, double back, very cheap, 58s. 6d.—Pres'and, Claverham, Berwick, Sussex.

Mewher's latest half-plate portable double extension camera, extends to 20 inches, double swing back, cross fronts, stereo division and front, three double backs with safety shutters, solid leather case, Ashford tripod, 9 in. aplanat, working at f/6, by Suter, of Bath, and Wray wide-angle landscape lens, 7½ in. focus, quite new, been used only a few times, cost £20, will take 14 guineas.—No. 325, office of this paper, 1, Creed Lane, E.C.

**Sundries.**—Surplus stock to exchange for good half-plate burnisher.—Arthur Jane, Bodmin.

Splendid genuine American organ, 11 stops, coupled in bass and treble, two knee swells, 6 ft. high, £12.—M., 30, Dunlase Road, Lower Clapton.

## WANTED.

**Burnisher.**—Burnisher, in good condition and cheap.—127, Dudley Road, Grantham.

**Lenses, etc.**—Wanted, an 8½ by 6½ lens, either Dallmeyer's new series extra-rapid rectilinear No. 4 or Ross's universal symmetrical. Must pass Editor of AMATEUR PHOTOGRAPHER. Lowest price for cash to M. Simpson, Priory Road, Aston, Birmingham.

**Rollholder.**—Wanted, a quarter-plate rollholder of latest pattern.—H. Norris, 15, Seymour Grove, Old Trafford, Manchester.

**Stereoscopic Apparatus.**—Wanted, Chadwick's stereoscopic camera. State particulars and price to No. 323, office of this paper, 1, Creed Lane, E.C.

Stereo camera, with or without lenses, good condition, reasonable.—No. 327, office of this paper, 1, Creed Lane, E.C.

Stereo lenses, paired by good maker.—No. 326, office of this paper, 1, Creed Lane, E.C.

**Sundries.**—Wanted, vols. 1, 2, 3, 4 of AMATEUR PHOTOGRAPHER, unbound and clean; state price.—No. 324, office of this paper, 1, Creed Lane, E.C.

Wanted, AMATEUR PHOTOGRAPHER posted regularly weekly. State lowest terms to Copeman, Henstridge.

**Bargains in Cameras and Sets.**—15 by 12 double extension camera, leather bellows, rising and falling front, wide-angle movement, fitted three double slides, as new, take £8 8s.; 12 by 10 camera, double extension leather bellows, wide-angle movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide, changing box, for 24 plates, also changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; 7½ by 5 camera, by Gotz, double extension, wide angle, and all latest improvements, double slide, very fine rapid rectilinear, Waterhouse

stops, and folding stand, £5 15s.; half-plate Star camera, by Morley, Spanish mahogany, wide angle, double extension, three double slides, fitted Optimus rapid rectilinear, four-fold stand and case, £7 10s., worth double; half-plate 1892 Instantograph camera, as new, all improvements, fine rapid rectilinear lens, Waterhouse stops, double slide, and folding stand, £7 2; half-plate International, finest order, all movements, Lancaster's lens, iris stops, instantaneous shutter, two double slides, stand and case, £4 4s.; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; quarter-plate Underwood's instanto, finest order, changing box for 12 ¼-plates, good lens, rotating stops, one slide, folding-stand and case, 35s.; 1891 Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Hand Cameras.**—Swinden and Earp hand-cameras, carries 20 quarter-plates, fitted Taylor and Hobson's best rapid rectilinear lens, roller-blind shutters and case, as new, £6 15s.; half-plate Lancaster's Rover, latest pattern, Lancaster lens and shutter, as new, 70s.; quarter-plate Rover as above, take 42s.; Ideal hand-camera, carries twelve quarter-plates, finest rapid rectilinear lens, two finders, etc., as new, £5 17s. 6d.; Stienheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Optimus detective camera, by Perken, Son, and Rayment, Optimus rapid rectilinear lens, carries six ¼-plates, covered black leather, take £4 4s.; Optimus magazine hand-camera, carries twenty-three quarter-plates, fitted Euryscope rapid rectilinear lens, instantaneous roller blind shutter, two finders, as new, take £5 15s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 17s. 6d.; and another, 15s.; Samuel's quarter-plate hand camera for twelve plates, quite new, rapid rectilinear lens, two finders, 32s. 6d.; All above warranted in very finest order.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium).

**Bargains in Lenses.**—10 by 8 Lancaster's rectigraph lens, Silver Ring, iris stops, as new, £3 7s. 6d.; whole-plate portrait lens, rack focussing, Waterhouse stops, works f/6, take 68s.; Ross' whole-plate rapid symmetrical, Waterhouse stops, works f/8, take 12s. 6d.; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross' actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; half-plate Ross' rapid symmetrical Waterhouse stops, grand definition, quite new, take £3 17s. 6d.; Ross' No. 2 portable symmetrical, finest order, rotating stops, take 45s.; Hookin's Desideratum, half-plate, Waterhouse stops, quite new, 10s. 6d.; Lancaster's half plate wide angle lens, rotating stops, take 10s. 6d.; whole-plate Suter No. 3, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; Ross' rapid symmetrical lens, as new, movable hood, Waterhouse stops, take £3 17s. 6d.; half-plate rapid rectilinear, half-plate, by Parker, Holborn, aluminium mounts, as new, take 30s.; Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d.; Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. ZELI, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of *Three Words for One Penny*) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

**"Amateur Photographer" Monthly Competition, No. 40.**—  
"PORTRAITURE AND FIGURE STUDY." Latest day, Sept. 19th.—  
Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, October 14th.)

The annual exhibition of the South London Photographic Society will be held on Thursday, Friday, and Saturday, 24th, 25th, and 26th November next, at Peckham Public Hall, Rye Lane, S.E. Four medals are offered for competition among members of the South Metropolitan photographic societies. Entry forms can be obtained from the Hon. Secretaries of the societies, or Mr. C. H. Oakden, 51, Melbourne Grove, East Dulwich, S.E.

We are requested to state that the Fairfield Camera Club has removed to their new rooms at the High School, Radstock Road, Elm Park, Fairfield. All communications to be addressed to the Hon. Sec., S. H. I. Smith, 17, Bentley Road, Prince's Park, Liverpool.

The Essex Cycling Union, which is an association for the furtherance of social intercourse between the various cycling clubs of the eastern county, proposes to hold an Inter-Club Lantern-slide Competition, at the "Wilfrid Lawson," Woodford, on 15th October. The following are the rules and conditions:—

(1) The competition to take place Saturday, October 15th, at "Wilfrid Lawson" (large hall), 7 p.m. (2) The proceedings to be interspersed with music; ladies invited to attend. (3) The competition to be open to clubs using the Essex roads (whether affiliated to the E.C.U. or not). Competing clubs to contribute twelve slides each, which may be of any subject, and must be the work of *bona-fide* members of the club, amateur photographers. (4) The definition of an "amateur" to be one who does not use photography wholly or partially as a means of living. The slides may *not* be professionally mounted, and to be ordinary lantern size. (5) An entrance fee of 2s. 6d. per club (or 1s. 6d. to affiliated clubs) to be charged. (6) Three valuable prizes are offered to the clubs providing the best exhibits. Three experts will be obtained as judges. (7) Arrangements, etc., for admission to the concert and exhibition will be announced later. (8) Entries must be made by September 10th, and slides must be sent in one clear week before date of exhibition. N.B.—All communications respecting the camera competition must be addressed, W. Charles Russell (Assistant Secretary), 9, Morpeth Road, South Hackney, N.E.

There are doubtless many of our readers who, being members of a cycling club, combine photography with wheeling, and the above will interest them.

We are now receiving numerous specimens of work done at the Convention at Edinburgh, and foremost amongst them we have some very good snap-shots taken by Mr. F. W. Hindley with Fallowfield's "Miall" hand-camera; one in particular of Miss Catherine Weed Barnes, bestowing a

smile on the snap-shooter, is a very good likeness. We hope to be able to reproduce two or three of these shots in our next Illustrated Supplement.

Messrs. Morgan and Kidd, of Richmond, the well-known bromide paper manufacturers and enlargers, have also sent us a very good enlargement of the Convention group, which is really a capital piece of work, and speaks well for the paper and the negative from which it was made.

REFERRING to our note on page 113 as to the forthcoming exhibition of the Bedford and District Camera Club, the Hon. Secretary writes to inform us that "since going to press with prospectus the Council of the above society have decided to add a bronze medal and two certificates in each class in addition to the medals already advertised."

THE Hackney Photographic Society will hold their annual exhibition at Morley Hall, Hackney, about the first week in November, on the same extensive scale as last year. The classes will be:—

(A) Members' work since last Exhibition. (B) Members' work before last Exhibition. (C) Members' work, Excursions. (D) Portrait and Genre (members). (E) Members' Lantern (six). (F) Open, Lantern Slides (six). (G) Members' Stereoscopic. (H) Open, Stereoscopic. (I) Open, Portraiture and Genre. (J) Open Landscape and Seascape, etc. Prints may be by any process, direct or enlarged—opals and transparencies excluded. Forms will be ready at end of September, and may be obtained on application to the Hon. Secretary, W. Fenton-Jones, King Edward Road, Hackney.

OUR publishers announce on another page the publication of "Studies in Photography," by J. Andrews, B.A. The author in his preface states that "in the first few chapters of this book I have endeavoured to consider the claims of photography to rank as an original art," and in subsequent chapters he has given numerous practical hints. The work is illustrated with six collotypes from the author's negatives. The book contains 200 pages, and is divided into sixteen chapters, which treat of "artistic photography, art in relation to photography, naturalistic photography, photography and colour, light, the artistic use of a hand-camera, composition, light and shade, perspective, photography and science, the study of nature, the study of art, portraits, atmosphere, five photographic factors, round about Jersey with a hand-camera."

The work will be found useful as embodying good sound art principles, written in a clear and comprehensive manner, and with the illustrations forms a handsome addition to the library.

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

## Letters to the Editor.

### ADJUSTMENT OF HAND-CAMERAS.

SIR,—As Hon. Secretary of a photographic society it has been my duty from time to time to examine and report upon

various hand-cameras. As my experience with some of these may be useful to both manufacturers and users, perhaps you may consider the following notes worthy of insertion in your valuable journal.

Quite recently I had a somewhat high-price camera sent me by an eminent firm of manufacturers, with a request that I would show it before the society, test it, and report on it. After having made myself acquainted with its design and method of working, which were admirable, both as regards compactness, simplicity, and efficiency, I charged the magazine and sallied forth to fire the necessary shots.

So far all went most satisfactorily, and my favourable opinion of the camera was fully maintained.

On developing, however, troubles began; each one of the negatives being hopelessly blurred in foreground, middle, and distance, showing that no part of the picture had been in focus; there was no appearance of shaking, and when looking into the matter I soon discovered that the lens was about a quarter of an inch out of focus. The camera had adjustable focus; however, instead of the lens being in focus for distant objects when brought right back and having movement *outwards* only for near objects, in this case there was also a totally unnecessary *inward* movement of the lens, which latter caused the blurring, the lens having been pushed right back on the assumption that that was its proper place for distant objects, there being no indication to the contrary.

As this experience of hand-cameras is by no means new to me, and I believe of altogether not uncommon occurrence, I venture to suggest that makers should have each camera carefully examined by a competent and conscientious man, to ascertain:—

(1) That the lens of the fixed focus camera really gives a sharp image on the exposed surface.

(2) That the lens of adjustable focus camera is properly in focus for distant objects when pushed right back as far as it will go, and that the focussing scale for nearer objects be accurately marked and the pointer correctly placed.

(3) That the finders should accurately represent the view given by the lens on the exposed plate, and that truly vertical and horizontal lines should be drawn on the ground glass, and each finder to assist when photographing buildings and other objects having vertical or horizontal lines.

(4) In the design of all magazine cameras, I think provision should be made to prevent the possibility of continuing the changing after all the plates have been exposed; the last plate should, after exposure, be properly protected so as to prevent its being exposed twice.

These points would appear to be almost too obvious to require emphasising, but the fact remains that errors do occur, and probably under the most aggravating circumstances. I believe, therefore, that too much care cannot be bestowed in the first instance on these essential points, and if carefully attended to much discontent with hand-cameras, in every other way admirable, would entirely disappear.

I do not, of course, claim that my remarks apply to every manufacturer or to every camera, but I do assert that even the name of a firm of repute is not always a guarantee against errors of the kind mentioned. My advice, therefore, to every photographer who buys a hand-camera to take with him on his holidays, is that he should on no account leave home without having first, by actual test, ascertained that the camera is in every respect correct, and capable of taking sharply on the plate the views shown in the finders. By taking this precaution he may save himself much disappointment and annoyance when the day of development comes.—I am, etc.,

L. S. F.

### EXPOSURES FOR INTERIORS.

SIR,—I noticed in last week's "Editorial" answers that you recommended someone to give half an hour's exposure on a light interior. My own experience is that if the place is really light this would over-expose tremendously. As I have photographed in many of our cathedrals, I have enclosed a tabular statement showing the results of my experience, which may prove of use to others so inclined, if you can insert it. In every case I used an "Optimus" R.R. lens,  $f/32$  stop, and developed with hydroquinone, potash and soda, obtaining excellent results. Of course these exposures are relative; darker parts of the same church may take two or three times as long. Stained glass also must be allowed for, as

it lengthens exposure considerably. I may add that I found nothing equal to Eastman's negative paper for this work, although rather slow. The transparent film as now sold does not come near it, often showing halation quite as badly as glass. Since the firm discontinued its manufacture (which I have never ceased to regret) I have found Edwards's isochromatic films, of the medium rapidity, to yield the most satisfactory results. Backing glass plates seems to be nearly useless.—Yours, etc., W. H. H.

## CATHEDRAL INTERIORS—EXPOSURES.

Cathedral.	State of Light inside.	State of Weather.	Exposure.	Plate.	Result.	Remarks.
Canterbury	Good	Fine, bright	1 hour	Eastman paper	Fully exposed	Eastman paper is very slow
York	Fair	Cloudy	20 minutes	Iso. plates, medium	Do.	Stained glass accounts for the prolonged exposure
Winchester	Very light	Fine	7 or 8 minutes	Iso. films, medium	Do.	Longer for choir, about 1 hour
Durham	*Dark	Dull, wet	40 minutes	Eastman paper	Do.	Slow, but excellent negatives
Lincoln	Fair	Fine	20 min. to 1 hour	Do.	Do.	Much stained glass
Gloucester	Light	Do.	1 hour	Do.	Do.	Slightly longer for choir and ambulatory
Salisbury	Very light	Do.	7 minutes	Do.	Do.	Double this at least for choir
Exeter	Good	Fine, diffused	1 hour	Do.	Do.	Lighting very even
Worcester	Fair	Dull, wet	1 hour	Iso. films, medium	Do.	Nave is very dark, give longer
Ely	Do.	Fine	10 minutes	Eastman trans. film	Do.	Films very rapid. Choir darker than nave
Hereford	Nave good, very dark	Diffused light	10 min. nave, 1 hour choir	Iso. plates, medium	Do.	The darkest choir I have seen
Lichfield	Good	Fine	20 minutes	Eastman paper	Do.	The stonework is dark in colour
Rochester	Nave good, dark	Do.	10 min. nave, 20 min. choir	Eastman trans. film	Do.	Do.
Peterborough	Fair	Do.	1 hour to 20 min.	Iso. films, medium	Do.	Choir is dark
Wells	Good	Do.	10 min. to 20 min.	Do.	Do.	Much stained glass in choir, hence longer exposure
St. Albans	Do.	Do.	1 hour to 20 min.	Eastman paper	Do.	Do.

\* The Galilee chapel is well lighted, and ten minutes should suffice.

## A TRIP TO CHICAGO.

SIR,—Answering the enquiry of your correspondent *re* duty on introducing cameras into the United States, I append a statement of the Consul-General in London:—

"H. Snowden Ward, Esq.,

Memorial Hall, Farringdon Street.

"Sir,—In reply to your letter of the 17th inst., I beg to say that cameras in use, taken over by passengers, are admitted free as personal effects.—Your obedient servant,  
Jno. C. New, Consul-General."

I should like to remind your readers that I am making all arrangements possible for the comfort and convenience of those European photographers who propose to visit Chicago next year, and that if they will send me their names and address, I can probably give them much information and assistance that will be of value. In any case it will cost them nothing, and every extra name that we get, even of those who hope to go and are not certain, will greatly help us in obtaining special facilities for all.—Yours faithfully,  
H. SNOWDEN WARD.

London, August 22nd, 1892.

## Reviews.

*La Pratique des Projections. Vol. I.: Les Appareils.* By H. Fournier. Published by Gauthier-Villars et Fils, 55, Quai des Grands-Augustins, Paris. Price 2 fr. 75 c.

In this volume the author, who is well-known in France as a photographic author, has given us a very good treatise on the optical lantern and the various appliances used with it. A brief historical note opens the work, and after considering the optical principles and apparatus involved in the same, he gives us a good summary of typical forms of lanterns and all accessories.

The work is well up to date, clearly printed, and illustrated by numerous cuts and diagrams.

## Apparatus.

## FITCH'S FILM CARRIER.

MR. E. H. FITCH, of 34, Angell Road, Brixton, S.W., has forwarded us a sample of his "Perfect" Film Carrier, which we have given a trial during our outings this last fortnight, and found very satisfactory.

The film carrier is a piece of stout Willesden paper, coated on one side with an adhesive material on to which the film is firmly pressed with a pad or roller squeegee, and it adheres well, and when required for development may be easily stripped.

This carrier will be found of very great convenience, and from our experience we can strongly recommend it. The adhesive matter has so far shown no tendency to lose its tackiness.

## XYLONITE WELL DISH.

Mr. Fitch has also sent us a specimen of his new transparent xylonite developing dish, with well to receive the developer, so that it is unnecessary to touch the film or plate, as by tilting the dish the developer is received in the well, and the dish containing the negative may now be held up to the light for examination etc. This is a handy contrivance, and useful in all dark-rooms.

**South Shields.**—A meeting of amateurs was held on the 11th inst. to consider the formation of a photographic society. It was decided to form such a society, and the amateurs present set to work to elect the officers. It was decided that a deputation wait upon Mr. Parry to ask his acceptance of the Presidency, and after consideration, he determined to accept the invitation of the members. The new society has reason to be pleased at this decision. The initial meeting was well attended, and a further increase of members was added to the society at the meeting on August 18th. A very homely evening was spent in discussing difficulties met by the members in their photographic work. The following gentlemen took part in the discussion, viz., Messrs. Parry, Robson, Elliott, and Davidson. The next meeting of the society will be held at the same place, on September 1st, at 8 prompt. The President has kindly promised to read a paper. All communications, etc., must be addressed to the Secretary, Mr. Geo. R. Wood, St. John's Higher Grade School, South Shields.

## Photographic Procedure.

By E. J. WALL,

*Author of the "Dictionary of Photography."*

### SECTION VI.

#### DEVELOPERS AND DEVELOPMENT.

(Continued from p. 100.)

WE have considered in our last notes the modification of the ferrous oxalate developer for over and under-exposure; we shall now proceed to consider the modification of the developer for particular subjects.

*Developing Plates exposed on subjects with Great Contrasts.*—The methods to adopt for the reduction of contrast are easy and very efficacious, the simplest being dilution of the developer with water. The developer must, however, not be mixed as usual; it is necessary to increase the proportion of oxalate; if the normal proportion be 1 to 4, the oxalate must be increased to 6 parts, and an equivalent quantity of water, so that our developer would have the following formula:—

Solution of oxalate of potash	..	..	6 parts.
" " ferrous sulphate	..	..	1 "
Distilled water	..	..	7 "

It will be noted that *distilled* water is recommended; this is essential, as will have already been gathered from our previous notes as to the white precipitate of oxalate of lime being formed on adding common water to the oxalate solution.

In cases of very great contrasts the proportion of water may even be increased to 10 parts, and should the lesser quantity be used first and the high lights appear too quickly, the developer may be poured off and more water be added.

The second means is to utilise the solution of hyposulphite of soda, as recommended on p. 100 for under-exposed plates. The third method is that suggested by Eder and Lainer, which is the addition of a few drops (about five) of a solution of iodine and iodide of potash in rectified spirit to every ounce of the developer. This is the best agent to use for the reduction of contrast, but it must be carefully used or excessively flat results are obtained.

*Developing Plates, exposed on subjects Wanting in Contrast.* To increase contrast with the ferrous oxalate developer is not a difficult matter. The addition of bromide of potassium in larger quantities than usual will increase the contrasts, but more effective still is the addition of citric and tartaric acids, and if 10 per cent. solutions of these acids are prepared one may add from 10 to 60 drops of the solution to every ounce of the mixed developer.

#### THE CITRO-OXALATE DEVELOPER.

This modification of the ferrous oxalate developer was recommended by Abney in 1881, and it appears to possess equal developing power to the normal developer, and also the advantage that the mixed developer does not become so readily oxidised and will therefore keep better. The actual formula suggested by Abney was as follows:—

Neutral citrate of potash	..	..	100 parts
Ferrous oxalate	..	..	22 "
Distilled water	..	..	4.0 "

The mixture was boiled till perfect solution was effected. In the following year this formula was modified, however, by Abney, and two solutions suggested:—

#### Solution 1.

Neutral citrate of potash	..	..	70 parts
Neutral oxalate of potash	..	..	20 "
Distilled water	..	..	168 "

#### Solution 2.

Ferrous sulphate	..	..	30 parts
Distilled water	..	..	168 "

For use mix the solutions in equal parts.

We have noted the restrainers in general use with the ferrous oxalate developer, but besides these many chemical restrainers have been suggested, such as ferric chloride, alkaline chlorides, ferric oxalate, etc. On the other hand, numerous physical restrainers have also been used, but have given place to soluble bromides. Physical restrainers act merely by making the developer somewhat thicker or less fluid, and consequently the penetration of the film by the developer is retarded. To this class belong sugar, glycerine, dextrine, solution of gelatine and colloidin, the latter being formed by the action of sulphuric acid on gelatine.

There are numerous modifications of the ferrous oxalate developer to be found in our previous issues and in photographic text-books, but so little is this developer used now that we need not devote any more space to its consideration.

#### DEVELOPMENT WITH PYROGALLOL.

Pyro, pyrogallol acid, or more correctly Pyrogallol, has for many years been the favourite developer in England and America. Its physical appearances are pretty well known, and therefore need not be described. There are various methods of utilising this, either in the dry state, weighing or guessing the required quantity each time of development, or keeping the same in a stock solution of definite strength and measuring the required quantity out. It may also be used with various alkalis, such as ammonia, the carbonates of soda and potash, or even with the caustics or hydrates of the fixed alkalis. Then again there are various additions made to the developer which have for their purpose the prevention of staining, as a plain solution of pyro, when used with an alkali, very soon becomes oxidised, and deeply stains both the hands and gelatine film on the plate. It is also not so easy to keep stock solutions of pyro without any addition. The additions usually made to the pyro developer are sulphites or other salts of sulphurous acid. It is more usual to utilise these sulphites when one of the fixed alkalis is used rather than when ammonia is the alkali.

(To be continued.)

## General and Photographic Chemistry.—IV.

By E. C. CONRAD, F.C.S.

### THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.—(Continued).

#### COMPOUNDS OF HYDROGEN AND OXYGEN.

HYDROGEN and oxygen combine together to form two compounds, viz.:—

- (1) Water, or hydrogen monoxide,  $H_2O = 18$ .
- (2) Hydrogen dioxide,  $H_2O_2 = 34$ .

WATER, or *Hydrogen Monoxide*,  $H_2O = 18$ .—O. : Water is continually falling on the earth in the form of rain, which is the purest form of natural water, containing only some dissolved gases, but on sinking into the earth and reappearing as spring water it often holds a large amount of matter in suspension, and sometimes is also heated much higher than the temperature of the air. The surplus from springs and drainage from the surface form rivers, and these flow into the sea. M.: It has

already been pointed out that whenever any compound containing hydrogen is burnt, one of the products is water. By accurate experiments it has been demonstrated that there are two parts of hydrogen to one part of oxygen in water. It can be produced by the direct combination of its elements, or by passing hydrogen over a hot metallic oxide such as the oxides of copper or iron. Eq.:  $\text{CuO} + \text{H}_2 = \text{Cu} + \text{H}_2\text{O}$ . P.: Water is a neutral liquid, neither acid nor alkali, and is the greatest solvent known; that is, it is unsurpassed in its power of liquefying or forming solutions with solid and gaseous bodies, but there is a wide difference in the amount of different substances taken up.

*Solubility of Gases.*—Thus the four gases given below all dissolve in water at  $0^\circ \text{C}$ ., but 100 parts of water dissolve—

1.9	volumes of hydrogen
4.1	" " oxygen
179.7	" " carbon dioxide
114,900	" " ammonia

The solubility of a gas is affected by the temperature and pressure; as a rule, the warmer the water the less it dissolves, but the greater the pressure the more gas will be in solution. So water can be freed from dissolved gases by boiling.

*Solubility of Solids.*—Solids also show a marked difference in amount taken up. As a rule more of a solid is dissolved on an increase of temperature.

*Saturated Solutions.*—When a given volume of water has dissolved as much as possible of a particular substance it is said to be saturated and forms a saturated solution of the substance. To separate a solid in solution the water requires to be boiled until it is given off in the form of steam, and by stopping this action and allowing the remainder to cool down a point can be reached with most substances in which the substance in solution combines with the water remaining to form a crystalline compound.

*Water of Crystallisation.*—Such combined water is called water of crystallisation. These combined compounds are formulated thus:  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ , showing, that zinc sulphate is crystallised with seven molecules of water. Crystalline salts can be decomposed by heat, and generally part with the larger portion of their water at about  $100^\circ \text{C}$ ., but often hold the last molecule with great tenacity. Thus zinc sulphate parts with six molecules at  $100^\circ \text{C}$ ., but requires  $240^\circ \text{C}$ ., to drive off the last molecule; and to show this, the formula of the crystallised salt is written  $\text{ZnSO}_4 \cdot \text{H}_2\text{O} + 6\text{H}_2\text{O}$ .

*Water of Constitution, or Water of Hydration.*—This final molecule is named constitutional or hydrational water.

*Action of Heat.*—It is a general law that substances expand on being heated, and contract on being cooled, but water only partially obeys this law. If a volume of water at the temperature of  $100^\circ \text{C}$ ., is gradually cooled, it contracts as it loses heat until it reaches  $4^\circ \text{C}$ ., when it begins to expand again until it cools to  $0^\circ \text{C}$ ., when it changes to ice with a sudden and violent expansion. It is this increase of bulk at the moment of solidifying that bursts water pipes, etc., in the winter; the crack is made at the moment of freezing, but the water, being solid, cannot show itself until it melts, hence the popular but erroneous opinion that the thaw causes the rupture. It is this expansion that causes ice to collect on the surface, and being a bad conductor of heat it protects the water under it, otherwise all our rivers and lakes would be frozen solid in a hard winter, and our climate would be arctic.

By cooling water in a closed vessel in a state of perfect rest, it is possible to reduce its temperature to  $-15^\circ \text{C}$ . without its solidifying, but the slightest agitation will at once turn it to ice, and the temperature will rise to  $0^\circ$ . On heating water from  $0^\circ \text{C}$ . it will of course behave in the

opposite manner—contract up to  $4^\circ \text{C}$ ., and then expand to its boiling point,  $100^\circ \text{C}$ ., under ordinary temperatures, when it forms steam with a very great expansion. Under pressure, as in a boiler, water can be heated far above the temperature of  $100^\circ \text{C}$ . without forming steam; but as the pressure becomes enormous, very great care, and a number of safeguards, such as safety valves, etc., are necessary. Water only boils at  $100^\circ \text{C}$ . under a pressure of 760mm.; if the pressure is only 733mm. it would boil at  $99^\circ \text{C}$ ., and if the pressure was 787mm. the water must be heated to  $101^\circ \text{C}$ . A difference of 27mm. in atmospheric pressure causes a difference of  $1^\circ$  in the temperature at which water will boil. The temperature at which water boils is also influenced by its depth, and by the nature of the vessel in which it is heated, and other causes.

*Latent Heat of Water.*—All substances contain some amount of heat, which is necessary to keep them in the condition of gases or liquids, etc., and as this heat cannot be measured by a thermometer, it is said to be latent or hidden. If we mix a kilogram of water at  $80^\circ$  with a kilogram at  $0^\circ$  we get 2 kilograms at  $40^\circ$ ; but if we mix a kilogram of water at  $80^\circ$  with a kilogram of ice at  $0^\circ$  we get 2 kilograms of water at  $0^\circ$ . The  $80^\circ$  have been used up, or have become latent in turning the ice to water; they are required to keep the water fluid.

*Thermal Unit.*—It has been agreed to take as a unit of heat that amount of heat which is required to raise 1 kilogram of water from  $0^\circ \text{C}$ . to  $1^\circ \text{C}$ . We have seen that it took 80 of these units to turn the ice into water, so the latent heat of fusion of water is said to be 80 thermal units. The latent heat of steam is 536 thermal units.

*Purification of Water.*—Water being such a good solvent nearly always contains something in solution and sometimes in suspension. The latter can be got rid of by filtration, such as allowing it to percolate through unsized paper (the kind known as Swedish filter paper is the best), or the water may be boiled and the steam condensed. Water treated in this way is said to be distilled and is tasteless, and, if pure, will be colourless and inodorous, and give no precipitate with the following reagents:—ammonium sulphide, lead acetate, ammonium oxalate, barium chloride, and silver nitrate.

*Solubility of Salts in Water.*—The following list gives the principal soluble and insoluble salts, with the exception of the sodium, potassium, and ammonium salts, which are all soluble.

Names of Salts.	Soluble in Water.	Insoluble in Water.	Remarks.
Carbonates	None	All	—
Sulphates ...	Most sulphates, excepting:	Ba, Sr, Cu and Pb, and some basic sulphates.	—
Chlorides ...	All, excepting:	Ag, Hg, Pb, Cu, Au, Pt...	PbCl <sub>2</sub> is sol. in hot water; the last three are slightly soluble.
Bromides ...	All	Ag, Hg, Pb.	PbBr <sub>2</sub> slightly.
Iodides ...	All	Ag, Hg, Pb, Cu, Bi, Au, Pt.	PbI <sub>2</sub> sol. in hot water.
Nitrates ...	All	A few basic nitrates	—

*Solubility of the Oxides.*—The oxides of sodium and potassium readily dissolve in water, and the oxides of barium, strontium, calcium, and magnesium are slightly soluble. They all form alkaline solutions, which neutralize all acids. Eq.:  $\text{K}_2\text{O} + 2\text{HCl} = 2\text{KCl} + \text{H}_2\text{O}$ .

The oxides of arsenic and chromium and all the non-metallic oxides dissolve, forming acid solutions; the other oxides are insoluble.

*Action on Water of the Metals.*—In the preparation of hydrogen, we have given the action of those metals that decompose water at the ordinary temperature or steam at a red heat. The following metals are without action on water at any temperature:—As, Sb, Pb, Cu, Ag, Hg, Bi, Au.

*Hardness of Water.*—Water is said to be "hard" when it

contains anything in solution that prevents the lathering of soap. The carbonates of lime and magnesia are insoluble in pure water, but dissolve in water containing carbon dioxide, forming bicarbonates. Eq.:  $\text{CaCO}_3 + \text{CO}_2 = \text{CaCO}_3\text{CO}_2$ . In boiling such a water the bicarbonate is decomposed, the carbon dioxide being given off and the carbonate precipitated. It could also be thrown down by adding lime to the water, the action taking place as follows. Eq.:  $\text{CaCO}_3\text{CO}_2 + \text{CaO} = 2\text{CaCO}_3$ . Many processes for softening water on the large scale take advantage of this action. Sulphate of lime, etc., produce a hardness that cannot be removed by boiling, in which case the water is said to be "permanently hard." Those waters that are softened by boiling are said to have "temporary hardness."

**HYDROGEN DIOXIDE, or Hydroxyl,  $\text{H}_2\text{O}_2$ .**—This substance, which can be considered as water combined with an extra atom of oxygen, can be prepared by several processes, of which the following are examples:—

(1) By adding moist barium dioxide to a cold solution of sulphuric acid, and filtering off the precipitate. Eq.:  $\text{BaO}_2 + \text{H}_2\text{SO}_4 = \text{BaSO}_4 + \text{H}_2\text{O}_2$ .

(2) By adding barium dioxide to a cold solution of hydrochloric acid, and purifying the liquid by adding sulphuric acid, silver sulphate, and barium carbonate.

(3) By passing carbon dioxide into a mixture of barium dioxide and water, and filtering. Eq.:  $\text{BaO}_2 + \text{H}_2\text{O} + \text{CO}_2 = \text{BaCO}_3 + \text{H}_2\text{O}_2$ . Any of these methods will give a weak solution of the hydroxyl, which can be concentrated *in vacuo* over strong sulphuric acid.

**P.**: When concentrated it has a strong bitter taste, whitens the tongue, bleaches the skin, and produces violent itching. Its S. G. is 1.45. It remains liquid at  $-30^\circ \text{C}$ ., slowly decomposes at the ordinary temperatures, and rapidly at  $50^\circ \text{C}$ . It readily parts with half its oxygen, and acts as a powerful oxidizing agent, and in some cases as a reducing agent. It liberates iodine from its metallic compounds, but is without action on chlorides and bromides. The strength of the commercial preparation is expressed in the number of volumes of oxygen it gives off on heating; the usual strength is ten volumes. **U.**: It is a convenient source of oxygen and as a bleaching agent. **U. P.**: A very dilute solution of this reagent is useful for decomposing the last traces of sulphites or hyposulphite of soda that may remain in photographic films after washing, the following reactions taking place: The sodium sulphite ( $\text{Na}_2\text{SO}_3$ ) or hyposulphite ( $\text{Na}_2\text{S}_2\text{O}_3$ ) being oxidised into the basic or acid sulphate of soda, which are quite harmless. Eq.: (1)  $\text{Na}_2\text{SO}_3 + \text{H}_2\text{O}_2 = \text{Na}_2\text{SO}_4 + \text{H}_2\text{O}$ . (2)  $\text{Na}_2\text{S}_2\text{O}_3 + 4\text{H}_2\text{O}_2 = 2\text{NaHSO}_4 + 3\text{H}_2\text{O}$ . **Test.**—A solution of guaiacum and infusion of malt become blue in presence of even a trace of the dioxide.

## How to Make a Set of Photographic Apparatus.

By H. J.

### CHAPTER IV.

#### THE DOUBLE DARK SLIDE.

THE subject of this chapter is, I think, the most important of the whole set of apparatus, and requires the most careful work of any, but although it is of such a nature that it may be said that it is not possible for any amateur to make it properly so as to answer the purpose, I say it is quite possible, as I have done it, and therefore others may be able to do it if they try; and the dark slides being very

necessary as well as very expensive articles, I think that soon after this is printed there will be a few more who will say the same as I do.

There are several kinds of slides made, but the one that I am about to describe is the ordinary book form with folding shutter, as I do not think that these can be beaten for good practical use, though the fancy patents at fancy prices may perhaps be useful in relieving the pressure on some pockets as well as adding to others, so if no use for use, they serve their purpose in a way, and perhaps in some cases in the only way, they are intended to.

FIG. 29.

We will suppose that we are making three double slides for the cameras which I have described in my former papers; for these we shall require 17 ft. of grooving, or as it is usually reckoned in the double,  $8\frac{1}{2}$  ft. This can be bought ready made at eightpence per foot, but as it can be made cheaper, and is really not difficult to make if set about in the right way, I will show how to make it ourselves. It is best to make it in lengths long enough to cut one half of a slide, so that if there is any slight difference in the grooving it is not apparent, as we can use a length for each frame, and of course there will not be any difference in the grooves by so doing. Now to make the grooving we shall want a piece of one-inch mahogany 2 ft. 10 in. long, plane it both sides, and gauge it to a thickness; it must not be less than seven-eighths of an inch, and if it is a trifle more it will not matter so that it is the same throughout. Now square one edge, planing it straight at the same time; then along the edge, in the middle, run an eighth of an inch groove, one-eighth of an inch deep as well; then make a rabbet in one corner, an eighth of an inch on the edge, and barely an eighth deep (that is on the side of board); now turn the board down flat on bench with the above rabbet upwards, and run a

FIG. 30.

FIG. 31.

sixteenth of an inch groove, leaving the same thickness between the rabbet and the groove. When this is done, the board will be as shown in fig. 30, and on marking on an eighth of an inch beyond the last groove and sawing it off, and gauging it down to a bare three-eighth inch in thickness, it will be of the section as shown in fig. 29, and this is what we want. Having made one piece it will be comparatively easy to make the others, therefore I will suppose the other five to be done, and will proceed with making the frames. In order that the figures 29 and 30 may be better understood, I have lettered the grooves and rabbet, and it will be seen that the groove A is formed on the edge of board, and is for the reception of the small strip as shown, to prevent the light from entering between the frames when filled with plates. The rabbet B is formed on the corner, the widest part being on the edge of board; this rabbet is for the plates to rest in, one plate resting in each frame, with a division plate of metal or card

between. The groove C is formed on side of board, and is for the shutter to slide in when exposing the plate. I think that I have made this sufficiently clear, so the next thing is to make the small piece shown in fig. 29; this must be a bare quarter of an inch wide, and of the right thickness to fit somewhat easily in groove A. We shall only want three lengths of this, and when made, a length can be glued in the groove A of three of the lengths of grooving, leaving the other three as they are.

We will now see about making the frames. Place two lengths of the grooving together, one without the tongue and one with, so that the latter fits in the groove of the former; then place the two together in the mitre box, and cut off a length of  $8\frac{1}{2}$  in. The rabbet edges should be the shortest side of mitre (see fig. 32). Lay aside the length you have cut off, keeping the two pieces together, and cut the other piece so that the rabbet is at the shortest side of mitre still; then measure off a full  $4\frac{1}{2}$  in. from this short side, and cut this length off, reverse the mitre again as before, and cut off another length of  $8\frac{1}{2}$  in. (this is the length from longest point of mitre), and cut off square. Now cut the remaining piece, which will be about the right length, into another

short length the same as before,  $4\frac{1}{2}$  in. full at the shortest or rabbeted side. The stuff is now cut off for one complete slide, and before cutting more off this should be numbered so that the same pieces can be brought together again in case they get mixed, which they are very likely to do during the remaining operations. The remaining grooving can now be cut up and numbered in the same way. Now take three of the shortest pieces, or, as they must be separated, I suppose I should say six, and plane away all outside the groove C. The shaded part in one piece of fig. 29 shows the part to be planed away in all six pieces; this is done to allow room for the shutter to slide.

The mitres can now be shot on a shooting board, using a very sharp plane, and trying the first two that are shot to make sure that the board is true. If not, make it so, as then the whole lot will fit without any further trouble. All the short pieces must be brought to exactly the same length at the inside (the grooved edges), or the slides will not be alike. The square ends of the longest or side pieces must now be seen to. On these a mitre must be cut half way through from the inside. See fig. 32, D being the side piece; and fig. 33, which shows the edge of the same piece after the mitre is cut. All of the side pieces must be done in the same way, the distance between the short side of mitres being full  $6\frac{1}{4}$  in., and great care must be taken to get them all exactly alike. Now make a kind of shallow box wide enough to hold the whole of the grooving when placed on its edge, with the exception of the end pieces which were planed down; this will be about 7 in., and the same length will be long enough. It will need no ends, but must have sides standing up an inch. One end of the sides

must be cut to a mitre, and half way along the mitre make a saw cut at right angles with it going in about a quarter of an inch. Now place all the grooving in this box, with the mitred ends level with the mitred sides of box, and wedge it all tightly so that it cannot move; then with the same saw make a cut a quarter of an inch deep in each mitre. The cuts in box sides will serve as guides, and by doing them all at once in this way they will be all alike; the end pieces being mitred at both ends will require turning round and cutting again, but the

sides will of course only want doing at one end. The frames can now be put together; to do this, take two of the side pieces without the tongue, and screw one of the thin end pieces into the mitres which are cut half way through. See fig 32, E being the end piece, and D the side piece. Now do the same with other two sides and end, this time using those with tongue inserted; then take two of the thick end pieces, one with tongue and one without, also get some pieces of veneer of the thickness to just go in the saw cut in mitres, and cut them  $1\frac{1}{2}$  in. long, and  $\frac{1}{2}$  in. wide; now lay down the frame with the tongue up, lay the other on it with the groove down so that they fit together, then place the two ends together and put them in their places, and slip a piece of veneer in each saw cut; this will hold them together temporarily while the other two slides are done in the same way. When this is done make a length of wood (deal will do) of the section shown by dotted lines at F, fig. 31, 18 in. long; cut this into twelve pieces. Now have the glue hot and take one slide apart, glue the mitres of the thin end piece and screw in position again, then glue the two mitres of the other end piece, also the two side pieces, and place together and glue a piece of veneer and place in each saw cut; do the corresponding half of the slide in the same way as quickly as possible, and lay on the first one, putting a block or two between to keep them apart, and slipping the saw cuts over the same pieces of veneer, so that the veneer holds the two frames together. Now place an angle piece at each corner as shown in fig. 31, F F F F, pass a string round the four pieces three or four times and tie the ends together; then insert a nail or piece of iron in one fold of the string and twist it up tightly; this will be found to draw the mitres together beautifully, and must be left until dry. All the frames must be done as above, packing the two apart in each case, so that when the glue is dry the veneer can be cut asunder between the frames; if they were glued up close together, this could not

FIG. 32.

FIG. 34.

FIG. 35.

Fig. 33: A diagram showing a cross-section of a shutter frame. It is a rectangular frame with a central opening. The frame is composed of several pieces, with labels B, C, and C. A dashed line B-B indicates a cross-section through the frame. The central opening is labeled C.

be done without damaging them. When the glue is dry, the strings and corner pieces can be taken off, the veneer cut, and the frames cleaned off with plane and glass paper, and then the shutters can be made. These are made of quarter-inch mahogany, but as they would curl and twist if cut out of the board and fitted as they are, it would not do, so to prevent this they must be clamped. Now to any one who has a small circular saw, this is an easy job, as they could make them all in one and cut up after; but as it is not very likely that many of my readers are so fortunate, I must cater for those who will have to do it by hand. For the three slides we want six shutters; each of these must be made up of three pieces as shown at G H G in figures 34 and 35, the grain of the two outside pieces G G running lengthways of the shutter, and H running crossways; thus it is practically impossible for them to warp or twist. Now prepare six pieces of quarter-inch mahogany  $3\frac{1}{4}$  inches long

(the lengthways of the grain) by 9 in. wide, also twelve pieces 9 in. long by 1 in. wide. The  $3\frac{1}{4}$  in. of the former is exact measurement, the others not so exact.

The narrow pieces must be jointed, one on each side of the larger pieces; and when good joints are made in all of them, run a fine saw-cut down each joint as near the middle as possible, and cut some pieces of veneer to form tongues to fit in these grooves. The whole will be clearly seen on referring to fig. 35, which is a section of shutter and shows the tongues in the joints. The whole can be put together, first glueing the veneer and inserting it in the centre piece, and then glueing the two edges and putting them together. Rub them to and fro so as to get out as much glue as possible; this will make a good joint which will never break. When the glue is set, plane one edge of shutter so that the narrow piece is parallel, and from these edges square across about an inch from one end, and cut them asunder, and then make a saw cut in each piece as before, and bevel into the cut from each side, but instead of putting in a piece of veneer, glue in a piece of parchment or other light-tight material to form a hinge to the shutter; this joint is much better than brass hinges, as well as being easier made.

Two joints can be made in shutter if it is preferred, so that it will fold round back of slide when drawn, but I prefer the single joint so that the shutter lies along side of camera or at the top if using the plate upright.

The shutters can now be planed off level on one side and fitted, and then while in the slides the other side can be planed off so that it is level all over; then a small bead can be run up each side where the shutter and frame of slide come together.

The frames of shutters can now be hinged together with small brass butts put on at the end (I I, fig. 31), and while the slide is held together small notches must be cut as shown at K K, fig. 31; these are for the stop of shutters, as will be seen a little further on.

Now prepare six pieces of mahogany about 5 in. long by 1 in. wide, and one-sixteenth inch thick. One of these pieces must be glued on each shutter at the end which projects from slide and forms the handle. To find the correct place the slide must be opened out flat so that the inside of shutters are upwards; and the shutters being held in as far as they will go with one hand, with the other glue the thin piece on the projecting part, keeping it close to end piece of slide; this gives a better handle to the shutter and also prevents light from entering slide between the shutter and frame. The shutters can now be cut to the shape shown, making them all alike, and then when they are placed in slide face to face the handles will not come opposite each other, as if they did it would be awkward to take hold of.

The slides must now be fitted to camera by ploughing out a groove in each edge of the right size to leave a tongue, which fits in the groove formed by brass strips on reversing back, and after they are fitted, a pair of clips can be fitted to each slide as shown, fitting them in beyond the tongues on edges; a small turnpin must also be inserted in each frame of slide, which will turn over the ends of shutters and prevents them opening at the wrong time. The slides are now finished except polishing, the instruction for which I have already given and therefore need not repeat them here.

The focussing frame must be made so that the rabbit which holds the glass is the same distance away from the face of it as the rabbit of dark-slide is where the plate rests, or if this is not attended to, your pictures will not be in focus. The frame will also be keyed together in the same way as the frames of slides.

The following are the fittings required for three half-plate slides, with prices of same:—

	s.	d.
Three pairs clip hinges to hold slides together	1	0
Three pairs hinges (1 in. brass butts)	0	6
Six turnpins to hold shutters in	0	6
Screws included in above prices.		

## Study and Practice of Art in Field Photography.

BY A. HORSLEY HINTON.

(Continued from page 456, vol. xv.)

### IX.—ON THE TREATMENT OF DISTANCES IN LANDSCAPE.

Of those things which are popularly supposed to be beyond the possibility of photography to render truthfully there is, perhaps, nothing which is such a frequent source of regret and disappointment than those objects, or that part of the scene, which, being more or less remote from the point of view, are included in the comprehensive term *distance*. In how many instances the distance is the most charming feature in the landscape, and yet when seen on the camera screen this same distance is found to have dwindled away to insignificance, and the picture is abandoned with a feeling akin to despair.

This is, perhaps, the more keenly and oftener felt in pastoral and flat country where the distance does not consist of any very striking or prominent objects such as mountain peaks or rugged chains of hills.

Groups of trees and masses of foliage and lesser hill slopes, softly blended one behind another, with here and there a solitary or detached tree rising a little higher than the rest against the sky, may form a very pleasing boundary and termination to the receding planes of the level meadowland, either on account of the form which it assumes or for the constantly varying purples and greys which it takes from the changing light and shadow of the sky overhead. It does not occupy very much space, it is not in its elevation a very large thing, it comprises nothing bold or great, or striking, but it may be enough to complete, or even to make the picture, and to be quite essential to it; and yet in the camera it somehow diminishes down to a mere blue line, and you feel its loss in your picture at once. In consequence of this, such subjects are very often shunned and are regarded as outside the limitations of successful photography.

We believe most of our readers who have done any considerable amount of out-door photography will recognise the trouble we have indicated, and have either never inquired into the cause, or else without much consideration have put it down to one of the inherent errors of the lens.

Now, it may not be unprofitable if we endeavour to ascertain whether the error is not more apparent than real—if, indeed, error there be—and also to inquire why we feel the incapacity of the instrument to reproduce distance, and further, if possible, to create a happier and more contented frame of mind with regard to this particular phase of landscape work.

In the first place it seems to be popularly believed, by some at least, that the short-focus or wide-angle lens magnifies the foreground in proportion to the rest of the scene, and diminishes the distance—or, in other words, *exaggerates the perspective* of a scene—and that a lens of longer focus and narrower angle, of the so-called “rapid rectilinear” or “single view” type, possesses the power of rendering

distant objects larger, and therefore to the eye more naturally in proportion to the rest of the landscape. The fallacy of this belief may be seen from a simple experiment.

From a given position make two negatives, first with a "wide-angle" lens of, say,  $4\frac{1}{2}$  in. focus, and secondly, with a "rapid rectilinear" lens of something like double the focal length of the former. In the *first* we shall have a result something like the accompanying sketch No. 1, in which the distance is so small as to lose all value, and the grasses and other foreground objects look gigantic and unnatural. In the second we shall find our lens has included a much more limited view, with a result something like our sketch No. 2; and were the two plates not closely compared, or if the negatives be of different scenes, and just comparison therefore difficult, the concluding impression might be that our short-focus lens has a way of diminishing the distance and enlarging the foreground in a manner anything but conducive to the production of a pleasing picture.

We have supposed two plates to have been made from the same spot, but in the *first* instance a lens of short focus was employed, that is to say, a lens which admitted of our plate being much nearer to the aperture in front, through which aperture the view is received, and hence we included a great deal more of the landscape, and as an inevitable

consequence that part of the scene which alone is included on the *second* plate is represented on the *first* on a much smaller scale. The relative proportions of each part of No. 2 are accurately preserved in No. 1, but each and all are smaller. This might be shown by cutting out from No. 1 just that part of the view included on No. 2, and enlarging it up to the same size, when we should find the proportion of foreground to distance is the same. But besides producing the same distance on a smaller scale, and including a great deal more of it, from left to right, our short-focus lens will have introduced also a much larger area. Vertically, a great deal more sky, which is not so objectionable, and also a great deal of foreground, which is probably the chief cause of its offence and apparent error. On the same plate on which we have our distance, etc., represented on a very reduced scale, we shall also have the ground almost to our very feet, so that a single tuft of grass or herbage may be as large as hundreds of acres of forest and meadow land. Relatively to the whole scene included on the plate, the distance is necessarily much smaller, and *not to the individual objects*. Hence the further the aperture be from the plate—that is, the greater the focal length of the lens—the smaller landscape area will be included, and therefore

the larger will be the distant objects in proportion to the whole. For instance, standing in the valley some mile or so from the foot of a great mountain, it would seem to the eye, as you look at it normally, that the huge peak occupies, vertically, about a third of the entire scene, and yet on your 10 by 8 negative made from this same spot you find the mountain only measures about  $1\frac{1}{2}$  inches in height. Now cut your 10 by 8 print down to about 5 by  $4\frac{1}{2}$ , and if your visual and mental impression as to the mountain occupying a third of the height of the scene be correct, the reduced print should be a satisfactory rendering of the view, and if it be essential or desirable to employ the whole surface of the 10 by 8 plate then you must use a lens of such length of focus that it will only include just that subject matter contained in the print cut down to 5 by  $4\frac{1}{2}$ .

We have already said far more than we would desire upon the physical or optical side of the question, because for all such matters we must refer our readers to those writings which are expressly concerned with the technology of the apparatus we employ, but from the foregoing it will be seen that so far as the scientific accuracy of our rendering of distance is concerned, it resolves itself into a question of length of focus or the inclusion and exclusion of matter the presence of which disturbs the impression of relative proportions. But beyond the mere scientific accuracy, there is another factor in our rendering of distance which must be taken into account, but which is not easily dealt with, and that is that whilst looking at the mountain already instanced our mind is largely occupied with a sense of its loftiness, its magnificence, its overwhelming greatness, so that the impression left in our minds would probably far from coincide with the scene if mirrored in a looking-glass.

In the same manner, when crossing a level country, the eye may be delighted with the blue distance seen beyond the furthest hedgerow; amidst all the wonderful gradations of grey and blue, we trace the winding course of a far-off stream, bright like a silken thread through level marshes, and between dark tree clusters, small points of red and white, not very clear or distinct, are cottages and farm buildings, which fringe a smooth grass field, and nearly lost at times in the shadow of tall trees which grow dark and purple under a drifting cloud shadow, each hedge-divided field varies in tint, yellow, brown, and green, yet all suffused with a delightful atmospheric blue which robs everything of positive colour, and gradually envelops the still more distant regions in a mystery which the eye cannot penetrate. All this the mind loves to contemplate, and the eye is fascinated with; the admiration for this glimpse of distance overpowers for a time the attractions of the rest of the scene, and yet if we descend to plain measurements and facts we may find the depth of all this distance taken from the utmost horizon line to where the nearer landscape cuts it off is no greater, not perhaps so great, as the depth of yonder hedge of white thorn and bramble which separates us from the next field, and which we shall surmount by the easiest of wooden stiles. That part of the scene which the mind loves to dwell upon, the senses exalt to the suppression or diminution of the rest; and this power of exalting the painter artist possesses to a far greater extent than the photographer, if, indeed, the latter possess it at all. The painter in his portrait may draw the eye or the head, and in his landscape the mountain, slightly larger than it really is, and thus give additional importance to those particulars which the mind thinks larger than the eye sees them. How far the photographer's inability to do this is compensated for by the facility and rapidity of drawing which is so peculiarly his own, it is not our purpose to discuss here, but this part of our subject leads us to inquire whether after all many of our disappointments in pictures

of distances do not arise quite as much from a *lack of knowledge* of what is most beautiful and worth reproducing in Nature's distances, as from an inability to draw it as we wish, quite as much from our not having learned to *appreciate* that which is within our power as from any limitation, more or less imaginary, which we have accustomed ourselves to accept as among photography's failings.

An insufficient cultivation of the perceptions has stood in the way of artistic advancement amongst photographers all along, and it is perhaps nowhere more evident than in the treatment of landscape subjects in which a very distant scene is possible.

We submit that the distance which is pictorially desirable is not that far-reaching prospect which folks climb high hills or ascend into lofty campaniles to view. Spread out map-like beneath one, it excites admiration, but the strongest emotion awakened is a wonderment at the extent of the prospect, and what pleasurable sensations we may have owe their origin to astonishment rather than to the aesthetic. Neither is the whole or even the chief beauty of distance inseparable from the piling up of vast hill masses and mountain peaks towering skywards behind each other, so characteristic of some of the most popular picturesque districts of this and other countries.

The most powerful operation of distance in landscape is

the feeling of boundlessness which it creates; imagination escapes through the gap in the hedge to wander "across the far blue hills," not because of the hills themselves, nor on account of their colour or other particular, but because of their "far-offness." It is the feeling of freedom, the inducement to let fancy get away from those things which it sees clearly and understands, into the far-off distance where objects are only suggested and but half revealed; then there is a very sweetness where the sky meets the earth in a faint horizon line. All this will essentially be best observed and best felt in the flat open country where mile after mile, land, water, or varied vegetation, as the case may be, stretches away with little or nothing to interrupt our gaze, and yet to the average man who has never given the matter consideration the idea of any beauty in a distant prospect in a flat country would be received as almost ridiculous, and probably even the serious student will at first fail to wholly comprehend it. This is so chiefly because the untrained eye and taste seek for something striking and attractive which shall immediately appeal to and at once impress the senses.

Experience, however, teaches us that immediate impressions are less enduring in their power to please than those which arise after longer study and contemplation. Hence it will be found that the more we give attention to, and the more often we carefully notice, the comparatively quiet, unassuming distance which is found in flat country, the greater will be the charm discovered therein, and the

more will be found to excite admiration, even emotion. We have for our own part found it to be one of those ultimate and subtle impressions, the fascination of which never seems to grow less, and the more the taste is cultivated to appreciate, and the eye to observe these less pronounced, less revealed beauties, not only does our affection for them become stronger, but as there is less material to grow accustomed to, so there is little danger of our becoming wearied or troubled with a feeling of monotony.

Our purpose in thus writing at some length upon a matter which many will assert is after all largely a matter of individual taste, is because we would have our readers dispel the notion that it is essential that the distance to be satisfactory should comprise certain well-marked objects, or that a picture is unsatisfactory because much that is interesting is too remote and therefore too small.

Above all things remember that the chief and all-important thing about our distance is not its form or outline, or particular character, but that when reproduced in one photograph it should at once give the impression of *being distant* or far off. Remember that the idea of distance is not necessarily conveyed merely by objects being small, and smaller, gradually diminishing into invisibility. The landscape, as it approaches the horizon, looks increasingly distant because of the *atmosphere* which intervenes, an impalpable vaporous veil varying in all seasons and all climates, pervading everything; at nearest transparent, almost imperceptible, but the further the object the thicker the atmospheric medium which the eye must penetrate, thus imparting to remote objects the greyiness or the blue and purple which makes the distance so charming in colour and contrast, and of such softness and delicacy. If we render distance in our pictures without the most scrupulous regard for this important characteristic of distance, our best success in other respects will be worthless, and the effect untruthful.

In plain geometrical figures, such as houses and buildings, their perspective may be indicated by the arrangement of the component lines and parts, and to some extent this is done with such objects as hedges and roadways, which more or less tend towards rectilinear forms, but in an average landscape numberless objects are comprised, varying in nature, size, and figure, so that to express recedence or distance by drawing, that is by lines only, would be as unsatisfactory as incomplete; but in addition to this lineal perspective we have that aerial perspective, or the expression of relative distances by the suggestion of atmosphere, to which we have already referred, and upon this the right and truthful representation of nature mainly, and perhaps before anything, depends.

From the foregoing we would have our readers learn that after all, perhaps, the principal thing which makes distant objects desirable for our picture-making is the opportunity which is thereby afforded for the rendering of the atmosphere, under the influence of which each plane of the landscape gradually fades into indistinctness. Nowhere have we such opportunities of studying these effects as in a more or less flat and open country where the view is uninterrupted and unrestricted, and we have endeavoured to introduce a new purpose to our readers in the selection of picture subjects, namely, that the aim be not only the representation of pleasing forms and picturesque objects, but in selecting the scene we should be always careful to watch for those conditions of nature which give adequate opportunity for the representation of atmosphere, and with this object in view an interest and a beauty will often be discovered in a scene otherwise unsuspected of picturesque possibilities.

The presence of visible atmosphere being admitted as desirable in most cases for artistic effect, it follows that

those phenomenally clear days when the distance appears hard and sharp, and so distinct that it seems as it were to contradict itself by coming quite near to us, are just those conditions which, as a general rule, are undesirable for artistic photographic work, as is also the fierce and hard light of summer noon, which robs the scene of the idea of atmosphere and of "tone."

A flat, marshy tract of country passing by soft gradations from the clearness of the foreground through the remoter regions into the haziness of the far-off horizon, may, although comprising no very striking or important feature, form a better picture, and produce, upon the cultivated mind at least, a more enduring impression than the grandest and wildest landscape under less favourable conditions.

The study of "aerial perspective" and "tone" are inseparable, if, indeed, the two are not synonymous, and we shall take the opportunity of our next chapter of briefly referring to the subject of "Tone" before passing to other matters.

(To be continued.)

## The Theory of Development.\*

(Continued from page 126.)

### VII.—REPLY TO THE FOREGOING.

BY HENRY E. ARMSTRONG.

WHATEVER value my arguments may ultimately be found to possess, the discussion to which they have given rise clearly shows that it was highly desirable to co-ordinate the facts, and challenge an expression of opinion, and the objections which are raised to my mode of viewing photographic phenomena afford a most interesting indication of current opinion on such matters.

Mr. Elder thinks that little if anything is to be gained by regarding the changes attending the development of a photographic picture from an electrical point of view; Mr. Bothamley is in a state of indecision whether to accept an electrolytic theory of development or not; and Captain Abney apparently throws cold water on my attempt to draw a parallel between the De la Rue cell and a photographic picture in course of development.

It is very remarkable that, although nearly sixty years have elapsed, we have not yet learnt to appreciate Faraday's teaching, that chemical changes are essentially electrolytic phenomena, so clearly expressed in the following passages in his VIIth and VIIIth series of "Experimental Researches":—

"Those bodies which, being interposed between the metals of the voltaic pile, render it active, are all of them electrolytes, and it cannot but press upon the attention of everyone engaged in considering this subject, that in those bodies (so essential to the pile) decomposition and the transmission of a current are so intimately connected that one cannot happen without the other. If, then, a voltaic trough have its extremities connected by a body capable of being decomposed, as water, we shall have a continuous current through the apparatus; and whilst it remains in this state we may look at the part where the acid is acting upon the plates, and that where the current is acting upon the water, as the reciprocals of each other. In both parts we have the two conditions, *inseparable in such bodies as these*, namely, the passing of a current and decomposition; and this is as true of the cells in the battery as of the water-cell, for no voltaic battery has as yet been constructed in which the chemical action is only that of combination: *decomposition is always included*, and is, I believe, an essential chemical part.

"But the difference in the two parts of the connected battery—that is, the decomposition or experimental cell and the acting cells—is simply this: in the former we urge the current through, but it, apparently of necessity, is accompanied by decomposition; in the latter we cause decomposition by ordinary chemical actions (*which are, however, themselves electrical*), and, as a consequence, have the electrical current; and as the decomposition dependent

upon the current is definite in the former case, so is the current associated with the decomposition also definite in the latter.

"All the facts show us that that power commonly called chemical affinity can be communicated to a distance through the metals and certain forms of carbon; that the electric current is only another form of the forces of chemical affinity; that its power is in proportion to the chemical affinities producing it; that when it is deficient in force it may be helped by calling in chemical aid, the want in the former being made up by an equivalent of the latter; that, in other words, *the forces termed chemical affinity and electricity are one and the same*."

There is, however, no real difference between Captain Abney and myself; he prefers to take the zinc-copper couple as his model, but this is only another form of voltaic cell. In the case of the zinc-copper couple, no action can take place independently of the electrolyte or electrolytes in which the metals are immersed, and so in like manner no action would or could take place under ordinary conditions between bromide of silver altered by light, and the contiguous unaltered bromide, to which Captain Abney refers, until after the advent of the developer.

I am afraid that Mr. Bothamley has not appreciated my meaning. No experiments made by Hurter and Driffeld with which I am acquainted can be held to disprove the "electrolytic theory," and possessing as we do the records of innumerable experiments showing that electrolytic action invariably attends chemical change—that, indeed, the two are inseparable—no new experiments are required. The task before us is to decipher and interpret, and, unless we set aside Faraday's conclusions, there is no escape for us—we simply cannot avoid interpreting the facts in the light of an electrolytic theory.

Mr. Elder is clearly not a chemist, or he would not object to my attempting to decipher the mechanism of chemical interchanges, and there is not the least doubt that he and I consider the phenomena from entirely different points of view. As a chemist I cannot rest satisfied with an algebraic equation, but must endeavour to ascertain its inner meaning, and to trace to its origin each one of its terms. I can even justify my application of Ohm's law by reference to authority—that of Ayrton and Perry, in whose paper on the "Contact Theory of Voltaic Action" (*Roy. Soc. Proceedings*, 1878), it is stated that, "to connect the two ideas (of chemical affinity and the amount of chemical action) we have a third, viz., resistance, and the electrical law of Ohm becomes the chemical law—the quantity of chemical action in unit time equals the sum of a great number of terms, each of which is an electromotive force divided by a resistance."

With reference to the action of ammonia, I do not consider that it is different in nature from that of the fixed alkalis because silver haloids are soluble in it, but that, besides acting as an alkali, it has also an effect in consequence of its power of dissolving silver haloids. Mr. Bothamley forgets that in a gelatine plate the silver haloid particles are enclosed as it were in colloid bags, and that it is not to be expected that these would allow the silver compound to pass outwards. Development, however, takes place within these colloid bags, which, if they contain ammonia, must also contain a solution of the silver haloid in ammonia.

Both Captain Abney and Mr. Elder challenge my reference to the action of light as *electrolytic*. The fact that a silver haloid *per se* is unaffected by light—that it is not shaken to pieces as it were on simple exposure—and that action takes place only when a *sensitiser* is associated with it, appears to me to entirely justify my expression that "the action of light on silver haloids is strictly comparable with that of an electric current." I should, however, like to hear more from Captain Abney regarding the "more simple explanation which is given by considering it as a problem in molecular physics."

With reference to my suggestion that *perhaps* there are two distinct latent images, I am free to confess that this is a purely hypothetical inference. That an *oxy-haloid* image is formed it is hardly possible any longer to doubt, but it appears to me probable that a silver image should also result, in consequence of a change taking place similar to that which a silver haloid undergoes when electrolysed, especially as it is known that silver is formed when silver haloids are exposed to light in contact with reducible organic matters. As to the properties of silver oxy-haloids, no doubt we have everything to learn.

Regarding reversal, nothing more can be usefully said at present; the recorded facts require to be most carefully con-

\* From the Camera Club Journal.

sidered, and there is much need of further experimental enquiry on the subject.

There is not much, I think, in Mr. Bothamley's interesting addendum, which came under my notice after the above remarks were sent to press, requiring further special comment. I did not refer to his remarks with reference to the rendering of minute detail, as I did not wish to enter on a new subject; I will only say now that, in my opinion, such a circumstance affords no direct argument for or against an electrolytic theory. I hope to deal with the question on another occasion.

If Mr. Bothamley did not forget that the silver haloid was wrapped up in gelatine, he certainly did not fully realise the effect it would have. He now speaks of gelatine as a readily permeable colloid, and says that, if dissolved at all, the silver bromide would pass through the gelatine. I doubt this, as it appears to me probable that, as in a number of cases studied by Graham, the colloid septum would condition the decomposition of the soluble ammonia silver compound, and that, therefore, the silver bromide would not diffuse into the solution. My reference to the different effect of ammonia, I may add, was made almost entirely with the object of accounting for the tendency of the pyro-ammonia developer to produce a peculiar fog; I did not argue that as an alkali it differed markedly from other alkalis.

## How to Look at Photographs.\*

BY FRANK M. SUTCLIFFE.

PHOTOGRAPHS are generally said to show either technical or artistic excellence. Sometimes both qualities are visible in the same piece of work, sometimes they are not. There is another quality which ought to be present in all photographs, without which no photograph can be considered perfect; and, until this quality has been recognised, the photographer should stop before he pats himself on the back and says, "What a good boy I am," after he has taken what he may look upon as a perfect piece of work, as an example of technical skill, or as an attempt at picture-making. It may be clever, yet for all that it is a failure if it cannot *speak* to those who look at it.

There has been, as you all know, a lot of strife between what has been called the old school, and the new, or the sharp and the unsharpened; it seems to me that, if both these parties had looked at their work and at that of others in the right way, all this bickering would not have been. It would almost appear as if many consider their photographs as an end rather than a means to an end, and as if all that is expected of the spectator is that he should admire the skill of the worker as shown in his work; sometimes even it appears to be the *author* of the work who expects to be admired. Only the other day this was strongly impressed upon me. A youthful photographer was pointing out the beauties of what he considered a most successful picture, which he had just finished, to one of our oldest photographers, saying how he had been advised to place a figure at such a spot, but did not, because and because—Seeing the old photographer smile, he stopped in his oration, and, I hope, received a useful lesson when the old one said: "Pardon me for smiling, but I was thinking of a whipping I once got for falling into a horse-trough the very image of the one you have there." That old photographer knew how to look at photographs, for he was able to make them speak to him and recall to his mind bygone days. The person who looks at a photograph as a complete picture, unable to say anything about anything except the facts which existed at the moment of exposure, does not see very far. You may contend that, if this is true, it will depend more upon the spectator than upon the photograph, for what will give pleasure to one will say nothing to another. To be sure, if the spectator is blind to everything except the mechanical part of the work, the loss is his alone; but he need not, as he often does, call attention to his own ignorance by denouncing a picture a failure because his mind happens to be blank except so far as a knowledge of a certain kind of mechanics may go.

If a photographer thinks he can tell his tales better by making his works microscopically sharp, let him do so by all means; if any one's hobby is the study of mosses and fungi, no pinhole or spectacle-lens view will remind such an one of the happy days he has spent in poring over damp walls in musty nooks and corners. To some an extremely sharp picture may be positively painful, for it will perhaps disturb and break the chain of thought, whereas a less-defined one would allow the mind to wander at its own sweet will. At the last exhibition of the Photographic Society, the hang-

ing committee, the Secretary, and the judges had the opportunity of studying a few works which the rest of the world were not allowed to see. I don't allude to those which were hung on the floor, and afterwards consigned to the cellars, but to a small collection of pictures by the worthy President of this Convention. Among them was an almost ideal photograph. I don't mean that it was so uncertain and undefined that it could have represented anything the spectator might have been pleased to wish, but it was just enough to start the mind along a pleasant channel. The foreground did nothing more than carry the eye to the principal object, and when it got it there the eye was politely asked to take a seat, and the mind then began to entertain the spectator, and picture after picture were put before him; one heard the wind blowing and whistling through the mill sails, then it almost died away, only to come again in louder and louder gusts. Now the miller and his man come out and look anxiously, first at the yellow sky, and then at the wands, from which they take in nearly all sail. Yet the big arms rush round at a fearful rate as the sky gets darker and darker; what an enormous size the mill looks—did you ever go underneath a mill's sails in the dark? What terrible things the arms are—they are more like a nightmare than anything real, as they come down threatening to crush you at every turn, yet never getting any nearer. Then, perhaps, you awake from your dreams, only to find yourself inside the mill on a bright summer's morning, where the snowy whiteness is but little less dazzling than the sunshine outside. You notice how spotlessly clean the floors are polished by an unending stream of golden grain; your nostrils drink in, with infinite delight, the scent of newly ground wheat. Perhaps the miller weighs you in the big, old-fashioned floury scales, in which have been weighed, in good years and bad, the daily bread of the whole village. All this, and much more, did Mr. Davison's simple photograph say. Had it been taken by one of the cast-iron school, the same pleasant train of thought might have followed, if (mark the "if," if you please) one could only have kept at a distance of ten yards; but where is the man who is content to look at a photograph from this distance? No, it would have drawn us nearer and nearer, and every step would have disturbed the train of thought by forcing other subjects forward. Most likely the excellence of the lens would have been impressed upon us, and, once started on such a subject as cameras and lenses, good-bye to all pleasure.

You may think a windfall is a very suggestive subject—almost alive, as it were—and that it is only natural that it should have a story to tell. Very well, then, take photographic portraiture, or likeness-taking, as it used to be called. Which are the successful portraits? Those which are most beautifully posed, most brilliantly lighted, and most elegantly retouched? Not a bit of it. The best portraits are those which remind us in the happiest way of the originals. Those sitters who go to be took only to please themselves are invariably disappointed, and "serve 'em right;" for who, in their senses, wishes to be reminded of themselves? Or take views or a change. Why do people buy local views? Are they allured into spending their money because they are offered such exquisite examples of photographic art? No; all the tourist wants is something to remind him of the places he visits, something to strike a note in his memory. A few years ago I took a view, but somehow or other it did not sell at all, though it was as clear as the most fastidious could wish for. No; the view which sold was taken by the other man, though he ought to have been ashamed of it, for the grass was black, and his whites were white without any mistake. But his prints sold; do you know why? At one corner of his view was a white-washed public-house. I learned afterwards that visitors called there to refresh. My view did not include that ugly public-house. What I gained in artistic excellence I missed in sentiment and £ s. d.

There is another class of work which should certainly be able to speak. I mean subject or *genre* pictures; but these sometimes fail to appeal to anything but the spectator's sense of humour, so narrow is the line which divides the sublime from the ridiculous.

Turn to whatever branch of photography we will, it is hard to find one that does not provide ground for our airy palaces. You have all heard of the man who had been so badly brought up that

"The yellow primrose by the river's brim  
A yellow primrose 'twas to him,  
And nothing more."

Somewhere on the walls of this room you will find a photograph of some animals—sheep and lambs. Now, this little photograph will most likely say to you what the yellow primrose ought to have said to the unfortunate man. It will remind you of the days when you were young and innocent as the lambs; it will remind you of successive spring-times, of the birth of many happy years. Young lambs always remind me of a photographer I knew when a boy. He was always singing—

"If I'd as much money as I could tell,  
I wouldn't go crying, 'young lambs to sell!'"

\* Taken as read at the Photographic Convention.

He had, like many of us, mistaken his vocation, and was consequently miserable.

If possible, whenever you look at a photograph, try to forget the photography. An architectural photograph will preach no end of sermons in stone to one who is well versed in the history of architecture, but to one who knows nothing of this art it will only tell of small stops, wide angles, and the like; it will supply him with less mental food than the view of the lambs would to a man who had never known the country, to whom sheep and lambs only meant mutton chops and lamb and mint sauce.

No doubt you are thinking, Who do you expect has time nowadays for all this dreaming? and will be saying that you want your pictures ready made without being at the trouble of making them for yourselves. If these are your thoughts, I am afraid you find the world a very hard place, for, if you take away the "make-believe" with which life is coloured, you must make existence almost unendurable.

Those among you who are unable to agree with what I have said will, I think, at least admit that it is better to take your photograph first, and then build your ideal on it, than to raise your ideal and then expect to be able to take a photograph to come up to it. I will, if you will allow me, give you an example. A customer of mine wanted his shop-front taken. By the way, shop-fronts are about the only things the amateur has left for us poor professionals to take. Well, I took the shop-front, but it failed to please. Why? Because my customer expected the photograph to rise as high as his imagination did. When I asked him to point out the faults, he said that, in the first place, the young lady looking out of the window was too short and fat, not tall and graceful, as she should have been. Secondly, a wax figure he expected next week for the window did not show in the photograph; but his principal objection was that a gilded sky-sign, which he intended having put up next winter, was not in my picture.

May I say that a photograph gives us the naked truth, which has to be clothed by the imagination.

## Harmonising Harsh Negatives.\*

PROBABLY the most scathing and unanswerable criticism upon pictorial photography is that our prints are too black and white, too violent in contrast, that when viewed at arm's length they appear to be masses of black and white without relief in the shadow, or gradation in what should bethe lighter half-tone; or if both are to some extent secured, the general effect is poor and flat. This criticism, though not applicable to the pictures produced by our better workers, is, unfortunately, too true when applied to the prints made by the majority of our rank and file, among whom I may claim to have a place.

The cause is not far to seek. A moment's reflection will serve to show that no process can reproduce nature's black, the total absence of light, as in the case where our darkest shadow is, some spot where light cannot penetrate, nor can it reproduce nature's highest light—light itself, or light reflected from water or other bright surface. Our deepest black and whitest paper fall far short of these extremes, and even if it were possible to secure in a negative the full scale of light and shade as seen in nature, it is certain that no printing process on paper can give the gradation found in a strong negative.

If we expose a plate rich in silver, and preferably isochromatic, on some well-lit subject, showing deep shadow in the foreground and having strongly defined clouds in the sky, and develop in the ordinary manner, we shall have a negative in which the shadows are nearly clear glass, and the cloud forms, though extremely dense, will yet be clearly perceptible. On making a print we shall find that long before the faint shadow markings in the clouds are impressed upon the paper, possibly even before the distant portions of the landscape are visible, the darker half-tone will be one mass of black. Our printing process is only capable of rendering one end of the long scale of light and shade in the negative. Some compromise must be attempted. Artists have their own methods of overcoming the difficulty and vary them to suit their subjects. In some cases they may use up the longer portion of the scale at their command in translating the lighter half-tone, and compress the shadows into the remaining portion. In another case they may employ the opposite method, the shadows and darker half-tone may be fully rendered, and the lights com-

pressed. In a third case the whole scale may be uniformly compressed within the limits of the medium of expression; but the favourite method appears to be to introduce two or more scales into the composition, with the result that while the lighter half-tone may be much darker than in nature, yet the local contrasts being preserved, the painting or drawing conveys to the eye much the same impression it would receive from the scene in nature.

It is for us to consider to what extent we can make use of these methods in photography.

When we mask the landscape portion of a negative to allow the clouds to print out, or when we combine in the prints clouds from another negative, we are introducing two scales of light and shade into our composition. Masking and double printing or sunning down parts of the print are the readiest methods of obtaining harmony in what would otherwise be harsh prints. But when the lights and shades are intimately mingled, masking is difficult, and sometimes practically impossible, and the results of sunning down are sometimes far from pleasing.

If now we attempt in making the negative to compress the full scale of lights and shadows within the limits of our printing process (and this is quite possible by the method recommended by Captain Abney, *i.e.*, by developing first with full quantity of ammonia and just a trace of pyro, and continuing the development of the ghost image so obtained with full quantity of pyro and little ammonia), we are met with another difficulty—that of flatness—and there I would like to quote from an article in the *Photographic Quarterly* for April in this year, entitled, "Nature's Light Scales as Rendered by Photography," by Mr. H. Dennis Taylor. Mr. Taylor says, pages 180, 181, and 182:—"... the eye's appreciation of rather high contrasts and great variations in them is clumsy and discriminating; extreme contrasts from 1 to 10, or, better still, 1 to 20, in a photographic print yielding to the eye much the same sort of impression as extreme contrasts of 1 to 50, or more, in nature would yield, especially when the print is not directly compared to the original scene. But it was also shown that although to the eye one high contrast is much the same as another high contrast, nevertheless the eye is extremely sensitive relatively to variations in those moderate contrasts which exist between contiguous features and details of natural view, and which give them their distinctness and relief."

"Hence it follows that, while such extreme contrasts as 1 to 15 or 20, which are available in a photographic print, will do very good service for giving an idea of very much higher contrasts existing in nature, still those moderate and delicate contrasts existing between the essential details of the natural view cannot be lowered in value (by that compression of the light scale which is necessary and unavoidable in the print) without the eye being at once struck by the divergence from reality, and being disappointed by a flatness and want of vigour which does not do justice to the original." And again, as a still more telling illustration or proof of the above statement, let a long series of small rectangular spaces be imagined in immediate contact, each being exactly  $1\frac{1}{2}\%$  (or 2 per cent.) brighter than its neighbour on the left. If there are 325 of these strips, the photometric contrast between the darkest on the extreme left, and the brightest on the extreme right, will be as 1 to 100. Now a difference of 2 per cent. in brightness between two strips in immediate contact is easily perceptible to ordinary eyes, therefore all the strips would be clearly distinguishable from one another, and would constitute the *details* of the series. Now let a photograph of the series be produced in such a manner that the contrasts between the two extreme strips is reduced from 1 to 100 down to 1 to 5 (a trifle over). The light scale is then very strongly compressed, and it then follows that the contrast between any two contiguous strips will now be reduced to 1-200th, or a difference of one half per cent., instead of 2 per cent. as before. Now it has been proved by careful experiments with the experimental top, that such a small contrast as this is absolutely imperceptible to ordinary eyes. Therefore it follows that the rectangular strips will no longer be discernible, and that the whole effect would be that of a gradual and unbroken shading from one extreme of the series to the other. In other words, the details of the original have been altogether obliterated by the compression of the light scale, although a passable degree of contrast between the extremes is still preserved. The pith of the matter may be summed up thus:—While photography enables one to compress a very extensive natural light scale into the much narrower limits at the command of the printer, still it

\* Read before the North Middlesex Photographic Society, by J. McIntosh.

performs the operation in a strictly mechanical and accurate way by modifying all contrasts, great and small, according to photometric laws; whereas human vision does *not* estimate or appreciate natural and artificial contrasts in a manner directly related to their photometric values, but is far more sensitive to modifications in the smaller contrasts than it is to modifications in the greater contrasts."

(To be continued.)

## PHOTOGRAPHY AT THE BRITISH ASSOCIATION.

THE grants of money that were voted at the last meeting of the General Committee included one of £10 for photographs of meteorological phenomena, and one of £10 for photographs of geological interest.

### PHOTOGRAPHY AS AN AID TO THE SURVEYOR.

In the Geographical Section, Colonel Tanner introduced this subject. He stated that it was a question that of late had received some attention, and he gave the results of a series of experiments he had been carrying out.

Rectilinear lenses as now made are capable of yielding the natural features of a landscape without any appreciable distortion, and, taking advantage of this, Colonel Tanner constructed a transparent grating or scale graduated to inches, tenths, and fiftieths, which when superimposed on a photographic plate rendered it easy to measure up to one-hundredths of an inch the horizontal distance between any two objects on the plate.

In order to obtain the value in arc of one inch of plate Colonel Tanner devised this system:—He marked on the ground-glass of the camera two lines six inches apart, and with the camera levelled, and set at the astronomical focus of the lens, he set up signals exactly coincident with the two marks on the ground-glass. Then, taking down the camera, and setting a theodolite up in its place, he measured the angles between the signals, and so had a measure in arc of one inch of plate. This procedure was necessary because the makers of photographic instruments fail to mark on the sliding board of the camera the astronomical focus of the lens as furnished by the optician, and owing to the "depth" of focus of lenses a very considerable error may be made in finding the exact distance up to which the camera should be opened out so as to place the plate at the true focus of the lens.

The grating, graduated to inches and decimals, is capable of being used with any lens after the value per inch has once been determined and tabulated for use.

The views of practical surveyors as to the application of photography to survey operations differ very widely. While some would condemn the use of the camera *in toto*, others seem inclined to make it take the place of nearly every other instrument used by the topographical surveyor. Colonel Tanner pointed out that in its right place, and merely as an adjunct, photography might be made a very great aid in certain circumstances, and while for the survey of ordinary hilly country he did not see how the camera could be used with any advantage, yet in the case of the Himalayas and other high mountain ranges, he thought that a camera furnished with a rectilinear lens might enable an observer to secure work of a fairly high quality when time or circumstances might be against the use of any other instrument.

In the discussion which followed, Colonel Godwin Austin endorsed Colonel Tanner's views, and being a well-known worker in the high altitudes of Ladak and the Kashmir Himalayas, was able to speak feelingly of the great difficulties under which he had often been obliged to carry on his operations. Mr. Thomson followed with some remarks, and the meeting closed with a vote of thanks to Colonel Tanner.

## Societies' Meetings.

**Burnley.**—At a meeting of the Council on the 10th inst., Mr. J. Butterworth, J.P., presiding, the proposal to hold an annual exhibition was discussed at length, and a committee appointed to report upon the matter. The Hon. Secretary (Mr. Sutcliffe) promised a large number of annuals towards the library, and several improvements were suggested to the society's rooms. An excursion was arranged to Liverpool on the 10th, but the day was unfavourable.

**Cornish (Camera).**—On 15th inst., before a large attendance of members and friends, Mr. W. Brooks, of Reigate, gave a lecture and demonstration of his well-known collodio-bromide process for transparencies. Mr. Brooks successfully developed several plates before

his audience, and afterwards exhibited a large number of transparencies of local views taken thirty years ago, and also some from his Windsor Castle series, which were greatly admired.

**Hackney.**—Ordinary meeting on 16th inst., Mr. Beckett presiding. The excursion for the previous Saturday having been affected by a wet afternoon, an excursion was arranged to Dagenham under the leadership of Mr. T. H. Roberts. Messrs. Salmon, Dando, and Nunn showed prints on the Ilford P. O. P., samples of which had been sent. In every case satisfactory results had been obtained; Mr. Dando stating that the bath he had used for toning was:—Hypo, 1 oz.; alum, 6 drms.; water, 8 oz.; let stand for a while until properly dissolved, shake up, then add in small quantities at a time a solution of 3 drms. carb. soda (crystals), in 1 oz. of water. Filter, then let stand for a day, then add 1 gr. chloride of gold and 2 gr. acetate of lead (previously dissolved in 1 oz. of water). Printing must be carried on to a rather deep colour. Mr. Roberts said he had obtained a brick-red colour in print by printing in sunlight. The Chairman said that Mr. Wellford had given a good formula for toning bath, consisting of 6 oz. water, 4 gr. of gold, 1½ drms. bicarb. of soda; this would tone fast or slow, according to quantity of water added. Mr. Debenham had stated that the more gold used in toning the greater chance there was of permanence. Mr. Hensler showed results on Paget plates. He had been troubled with splashes on them. The Chairman said it looked as if hypo had been the cause. Mr. Hudson presented the society with several old journals, and was warmly thanked. Mr. Poulson asked, would sulpho-pyrogallol be fit to use after two years? The Hon. Secretary said he had used some which he had had about that period and which had given good results. Mr. Bynoe then showed Messrs. Beck's new hand-camera, "The Frena." Cut films were used, and forty could be used in the camera without holders. Mr. Fitch had made films for them which would keep as flat as glass. The camera was small and compact, and was much appreciated. Mr. Bynoe then showed his own invention of printing frames. There was no shadow in printing, and, in answer to the Hon. Secretary, he said prints could not possibly shift. The discussion on the stereoscope then was resumed, and on the question of pairing lenses, Mr. Bynoe said an expert was required to do it. The Chairman had found colours blend very well by one picture being printed differently to the other. The discussion was continued by Messrs. Foulkes-Winks, Reynolds, Bruce, Capel, Dando, etc.

**Lewisham.**—At the meeting on 19th inst., Mr. B. Davidson in the chair, a very interesting paper was read by Mr. A. L. Henderson on "Stereoscopic Photography." He dealt with the subject from its artistic and mechanical standpoints, and fully explained the principles underlying this particular and charming branch of the photographic art. In the course of his paper he exhibited the camera he uses for the taking of stereoscopic views. Among the novel points embodied in the instrument the following may be mentioned:—A holdfast device for the camera legs, to keep them in a definite expanded form; a plumbing device for the swing-back; a sliding-front with two pairs of lenses mounted thereon, one pair long and the other short focus; a magnifying glass cemented to the focussing screen; lenses fitted with diaphragms, having a small lens mounted in each, so as to vary the focus of the combination as follows:—4½ in., 6 in., 8 in., and 10 in. upon the insertion of either one or other of the stops between the front and back elements of the lens; and lastly a very simple shutter for time or instantaneous exposures, as required. Mr. Traill Taylor took part in the discussion, and gave the meeting some very interesting particulars with regard to stereoscopic pictures, and illustrated his remarks by a number of prints which, with those brought by Mr. Henderson, were viewed through some very neat and efficient stereoscopes kindly lent by Mr. Chadwick, of Manchester.

**Southsea.**—At the monthly informal meeting of this society, held on the 17th inst., Alderman Ellis, J.P., gave a practical demonstration of the Autotype process of printing. The lecturer had brought with him a number of undeveloped prints, and proceeded to develop these before the meeting, explaining in detail the necessity for each step, and the manipulation required to produce perfect results. This process having hitherto been considered somewhat out of the range of amateurs, surprise was expressed at the simplicity of working and the beauty of the results. Their varied colouring and, above all, their permanency, should win over many converts. Great interest was evinced in the demonstration, and the lecturer was heartily thanked at its conclusion. Mr. Hunt passed round an album of views illustrative of life on an Indian coffee plantation, and Major Bruno showed a new printing frame (Newington's patent), which permits the examination of the entire print, and has a simplified clamping action. The excursion pictures obtained at the recent outing to Midhurst had been kindly judged by Messrs. West with the following result:—Figure studies: 1st, Mr. J. J. Thornton, "At the Stile." Landscape: 1st, Major Bruno, "A Summer's Day." The next excursion will be Romsey on the 25th inst.

**Todmorden.**—At the ordinary meeting on 16th inst. it was decided to hold an exhibition some time in October. Four new members were elected, making a total of forty-five since January last. After ordinary business several plates were developed, the subject and exposure being unknown to the person developing.

### SOCIETIES' FIXTURES.

Aug. 26.—RICHMOND.—Show of Prints.  
 " 26.—HOLBORN.—Lantern Night.  
 " 27.—TYNESIDE.—Excursion.  
 " 27.—WEST SURREY.—Outing to Carshalton.  
 " 27.—RICHMOND.—Excursion to Carshalton.  
 " 27.—OLDHAM.—Ramble to Oldham Walks.  
 " 27.—BRIGHTON AND SUSSEX.—Excursion to Bramber, Coombe, Botolph.  
 " 27.—LIVERPOOL.—Excursion to Rossett and Gresford.  
 " 27.—CROYDON.—Photographic Ramble.  
 " 27.—HACKNEY.—Bromide Enlarging.  
 " 27.—SOUTH LONDON.—Excursion to Hyde Park and Albert Memorial.

Aug. 29.—TYNESIDE.—Council Meeting.  
 " 30.—CLEVELAND.—Hand-Cameras.  
 " 30.—HACKNEY.—"Safety of Dark-Room Light," W. H. Sodeau.  
 Sept. 1.—LEEDS.—"Carbon Printing," Mr. D. MacIver.  
 " 1.—HEREFORD.—Excursion to Abergavenny.  
 " 1.—LONDON AND PROVINCIAL.—"Control of Gradation," W. E. Debenham.  
 " 1.—NEWCASTLE-ON-TYNE.—Excursion to Gilsland and Naworth.  
 " 2.—LEWISHAM.—"A Shilling's Worth of Photography," Thos. Child.  
 " 2.—RICHMOND.—Informal Meeting.  
 " 3.—PEOPLE'S PALACE.—Outing to Wanstead Park.  
 " 3.—CROYDON.—Excursion to Zoological Gardens.  
 " 3.—WARRINGTON.—Ramble to Higher Walton.  
 " 3.—NORTHAMPTONSHIRE.—Excursion to Harleston Firs.  
 " 3.—ASHTON-UNDER-LYNE.—Summer Ramble to Chester.

**Correction.**—On p. 22 of the "Amateur Photographer's Annual," for Brennaud read Brennand.

## To Correspondents.

All communications for these columns are to be addressed to The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by TUESDAY MORNING'S POST.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

### QUERIES.

5794. **Address Required.**—Can you inform me of any camera club within easy distance of Victoria, S.W., that gives lectures through the winter, whose subscriptions are within the reach of an ordinary working man?—HAL.

5795. **Copying.**—Can any of your readers inform me the best way to copy an old silver print? I have tried once with tissue paper over the top, but the grain of the paper comes out much too plain.—HAL.

5796. **Chloride Printing.**—(1) Could any brother amateur tell me the best way to mount the Eastman gelatino-chloride prints? (2) Why the Ilford gelatino-chloride prints, toning very well, when put into the fixing bath should turn a sickly yellow? I used borax toning bath. (3) What maker would supply me with a really reliable view finder under 3s.?—PERPLEXED.

5797. **Mottled Negatives.**—I have noticed in developing negatives (more than one in the same solution) that frequently they present a mottled appearance. Can any of your readers kindly tell me the cause of this, and the way to avoid it?—R. J. P.

5798. **Spotting.**—Can anyone kindly give me any hints as to stopping out small circular spots on negatives; also any hints as to retouching finished silver prints of small scratches or spots? Any information will be thankfully received.—SPOTS.

5799. **Condenser.**—I wish to construct clock-face condensers for enlarging, and also for use with the lantern alone. Would a 10 in. condenser give as good results for optical lantern as a 4 in.? Please give reasons if any.—ALPHA.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

### QUERIES UNANSWERED.

July 15th.—No. 5756.  
 " 22nd.—Nos. 5763, 5768.  
 " 29th.—Nos. 5777, 5778.  
 Aug. 5th.—Nos. 5779, 5780, 5781, 5785, 5786.  
 " 19th.—Nos. 5790, 5791.

### ANSWERS.

5718. **Enamelling.**—Clean a glass plate—an old negative glass or cutting shape will do—with French chalk, and polish thoroughly; now coat plate with

enamel collodion, and, having made a solution of gelatine, 10 gr. to 1 oz. of distilled water, slip collodionised plate and print carefully into solution of gelatine, avoiding air bubbles; bring print face downwards into contact with coated plate, remove from solution, and squeeze into optical contact, and allow to dry. When thoroughly dry raise one corner with a knife, and print will strip from glass bearing collodion film with it.—INQUISITIVE.

5789. **Ilford P.O.P.**—It is the use of too much sulpho-cyanide of ammonium.—INQUISITIVE.

5792. **N. Ireland.**—I think "Cantabrigia" had better stay at Portrush. It has several good hotels; the "Northern Counties" is about the best, the accommodation is very good and the charges are moderate. An omnibus meets most of the trains at the station. The Giant's Causeway is best reached by the electric tramway. There are several places on the way worthy of a picture. The tram runs along the coast, and at the Giant's Head and Dunluce Castle one or two pictures may be taken. At the Giant's Causeway there are two hotels. Kane's hotel is the cheaper of the two.—W. W. M.

5793. **Bromide Paper.**—It is both necessary and desirable. The acid clearing bath takes out the yellow from the whites.—INQUISITIVE.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S POST if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

W. M. G.—You can keep the pyro dry, and then get your accelerator made up as follows:—

Sodium carbonate (pure) .. ..	1 oz.
Potassium P. B. .. ..	1 "
ferrocyanide .. ..	1 "
Sodium sulphite .. ..	4 "
Distilled water to make .. ..	50 "

If you add 2 gr. of dry pyro to every 10 drm. of this you will obtain a very good developer. The carbonate of soda should be the pure recrystallised salt, costing about 6d. per lb, and the carbonate of potash is that of the British Pharmacopoeia, to be obtained from any chemist.

BARNETT.—Dip your fingers into solution of chloride of lime made by stirring an ounce of chlorinated lime with half a pint of water, or you can moisten your fingers and rub them with the dry chlorinated lime.

J. B. JONES.—Lead is a misprint for soda; the bath works very well with P. O. P.

W. PAYNE.—(1) Carbon prints are eligible for all competitions; we place no restrictions as to process, except enlargements, which are not admissible. (2) This is too much to answer here, we will write by post.

J. K.—The articles on "Enlarging" were commenced in our issue of March 4th, 1892.

S. DE MORGAN.—It is our intention to publish a special number with criticisms.

R. C. IVY.—We are afraid the only plan is to work a print off in bromide, and treat as you say. It might be possible by cutting a mask to allow the fogged portion to print more than the rest.

C. F. HUGHES-HALLETT.—At the beginning of this year we criticised all prints sent in, but so many objected on the ground that the bulk of the paper was taken up with uninteresting matter, that we adopted our present plan. We might consider issuing a special supplement next year. We will try and find your print and criticise.

E. J. R.—(1) A whole-plate lens can be used on a

half-plate, and as only the centre of the field would be used, it would probably not require stopping down so much as when used on a whole-plate; it might therefore require less exposure, but this does not depend upon the size of the plate but on the stopping down of lens. (2) The films would be quite suitable for India. (3) Fitch's or Edwards's. (4) Try the Fallowfield, from Jonathan Fallowfield, 146, Charing Cross Road. (5) The tabloids are suitable for India. (6) Hypo cannot be obtained in any other form. R. W. Greff and Co., 29, Mincing Lane, have a new fixing salt which is in a little more convenient form—a powder.

H. HOLT.—Always glad to have your prints. If a figure is wrongly placed, then it is not an improvement; this explains the seeming contradiction.

MILLERS DALE.—You will find an article on pp. 12 and 23 on toning prints which will probably help you. We shall also hope to have an article on the same subject next week, which will answer your questions more fully than we can here. You will probably get cardboard slides from Mawson and Swan, 33, Soho Square, W.

C. W. A. ROSSER.—Agar-agar was tried some years ago for emulsion work, but after numerous experiments abandoned, as the emulsion always set lumpy and showed curious marking, and the use of this substance is the subject of a German patent No. 56,573, which suggests the repeated warming and cooling of a solution of agar-agar, or separation of the clouding particles by mechanical means.

D. S. WHITEHEAD.—(1) Over-printed, and too many straight lines in it to be good. (2) Too much foreground, and the figures are too much in a row. (3) Here again your print is cut in two by the line of the weir, and has too much foreground. (4) Printed too deep. (5) Flat and poor; you have attempted too much in this, and the principal objects are too small. (6) Negative wants intensifying, and the lettering should have been more sharply focussed. (7) Good. (8) Ditto. (9) The shadow side of the face is too dark, it wants retouching, so as to soften the contrast. Your work shows promise, though in landscapes you try to get too much on your plate, and thus spoil it. Try for little bits rather than panorama, etc.

W. P. CRAIG.—Many thanks for paper, which goes in next week, we hope.

G. GORDON LOWDER (TIENTSIN).—We send letter for you to your agents. The fault of your uniform grey skies is not continuing development long enough. Either replace the caustic soda in your development with carbonate of soda, or else add more bromide to the developer; use less accelerator and develop longer.

W. H. H.—Many thanks for notes. Will you write a letter on your views of hydroquinone, so that we may publish the same, and we will add a rider to it?

W. G. MERRITT.—Your prints look as though the hypo or fixing bath was acid. Add  $\frac{1}{4}$  oz. of washing soda to every pint of fixing bath. They may also be over-toned. The circular patch in the centre of your negatives is what is called "flare-spot;" it may be caused by the stops of your lens being wrongly placed or else having worn bright. Return the lens to maker, and ask him to set it right.

BARRY GRIGG.—The spots look as though they were caused by particles of pyro having adhered to the paper. Are you sure that your cutting table and plate boxes are perfectly clean? Write again.

W. B. H.—There is an article on Pinhole Photography in the *Photographic Quarterly*, October, 1890; in the *AMATEUR PHOTOGRAPHER*, April 29th, 1891; and *Photographic Quarterly*, July, 1892.

ENTERKIN.—We have no further notes on Oban beyond what is in the Annual. Nor do we know of an hotel or lodging-house.

F. F. CADWORTH.—You do not state what paper you are using, or what toning bath. Wash your prints well in water before toning, and when the water drips from the print quite clear and not milky, tone.

W. H. BIBBY.—The print possessed considerable artistic merit, which, as you see, was heavily handi-

capped by want of technical skill, or through carelessness.

**H. F. LINGING**—(1) Possibly your stain is caused by non-elimination of the hypo. You might try Edwards's clearing solution formula of sulphate of iron, alum, and citric acid. (2) The best plan is to allow about an ounce of hypo to every sheet of paper. When the gold is exhausted, the half-tones tend to a greenish hue; do not throw the old bath away, but mix it with the new, when you will get finer tones.

**NEMO**.—It is rather difficult to eradicate the yellow stain. Try Edwards's clearing bath.

Sulphate of iron	..	..	1 oz.
Alum	..	..	3 "
Citric acid	..	..	1 "
Water	..	..	20 "

**C. BARNES**.—Try Platt and Witte, Birbeck Works, Ridley Road, Dalston; or Park, 5, Station Buildings, Acton Street, Kingsland; or Lonsdale Bros., 3, Cockridge Street, Leeds.

**TIN TACK**.—It is a well-known fact that ordinary platino type paper if exposed long enough in contact with a negative will give an image on immersion in water just like the Pizzighelli print and platinum paper.

**M. E. C.**—(1) The fault in your prints may be due to one of two causes—either insufficient developing or else the use of too strong a gold bath and fixing bath. For plain paper, weak gold baths and weak hypo baths should be used; half the ordinary strength is about right. But probably the first is the real cause. (2) The cause of yellow stains on prints is probably due to touching the paper with fingers contaminated with hypo. (3) The indistinctness is due either to over-exposure and too strong a developer, or else under-exposure. We could not tell without seeing negative. (4) Block the sky out by painting it over with some yellow gamboge paint after the film has been varnished. (5) It looks as though the negative wanted intensifying; the print is rather over-printed.

## Sale and Exchange

### RULES.

**CHARGE**.—Twelve words or less for Fourpence. Every additional three words, one penny. The name and address of the sender must be paid for.

A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.

**DEPOSITS**.—The money for goods forwarded on approval may be deposited with the Publishers of the AMATEUR PHOTOGRAPHER, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS**.—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

**COMMISSION**.—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT**.—All payments are to be by cheques of Postal Orders, made payable to **Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.**

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 3d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING**.—Apparatus may be sent to the EDITOR, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C., who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent. upon the sale price of the apparatus.

**Bicycles, Tricycles, etc.**—For sale, 52 in. bicycle, balls throughout, laced wheels, hollow rims, bent handles, oval backbone, plated and blacked, weight 35lbs., nearly new, built specially to order, price £5 10s., or exchange for camera or lens by good maker. —C. Field, 63, Dartmouth Street, West Bromwich.

**Cameras, etc.**—Half-plate Lancaster's Extra Special camera, with triple extension leather bellows and six double dark slides, nearly new, cost £6 17s. 6d., sell for £4 10s., or offers. —T. C. Hosking, 1, Baldwin Crescent, Camberwell.

Exchange Griffiths' lantern slide camera for lens, R.R. or wide-angle, or shutter. —Campbell, 2, Eblana Road, Belfast.

Half-plate camera, mahogany single slide, also lantern, 4 in. condensers, quarter portrait lens fitting both, 52s. —J. Laurie, 36, Fordneuk Street, Glasgow.

Lancaster's half-plate Merveilleux camera, double slide, Instantograph stand, lot 27s. 6d. —Sidney Allpress, Broughton, Huntingdon.

Camera, mahogany 7½ by 5 Woodbury Tourist, leather case, two double slides, best make and hardly used, £6 6s., cost double; deposit. —30, Stapleton Road, Bristol.

**Cameras, Lenses, etc.**—London-made high-class half-plate double extension camera, best leather bellows, reversing back, every necessary movement, one double slide, 47s. 6d.; very finest half-plate extra-rapid rectilinear lens, exquisite definition, Waterhouse diaphragms, 22s. 6d.; great bargains; approval. —Cyclist, 8, Kenilworth Road, Willesden Lane, London, N.W.

Gem camera, repeating back, mahogany, four lenses, twelve pictures on quarter plate, lock, or postage stamp size, 37s., or exchange Instantograph quarter-plate, without lens or shutter. —Dr. Finny, Norbiton.

**Hand-Cameras, etc.**—King's hand-camera, rectilinear lens, Thornton-Pickard shutter, full size finder, perfect condition, 55s. —17, Sedan Street, Walworth.

Fallowfield's Facile hand-camera, quarter-plate R.R. lens, 60s. —H. Jelf, 51, Clarence Parade, Southsea.

Kodak Junior as new, rapid rectilinear lens, instantaneous shutter, fitted with about 30 films, covered leather in case, take 45s. —Samm, 19, High Street, Mold, N. Wales.

Fallowfield's Facile hand-camera, R.R. lens, rotating diaphragm, waterproof cover, 70s., or offers. —Kerdell, 1, Hanover Park, Peckham.

Kodak No. 4, holds 24 exposures, 2½ by 3½, brand new, price £1 10s. —Lennard, 29, Clarence Street, Preston.

**Lenses, etc.**—7 by 5 Optimus Euryscope lens, perfectly new, cost £4 14s. 6d., sell for £3 12s.; also half-plate combination rectilinear lens giving three different angles, quite new, cost £2 2s., sell for 30s. —T. C. Hosking, 1, Baldwin Crescent, Camberwell.

For sale, rapid wide-angle Euryscope lens, No. 1 Voightlander, new series, iris diaphragm, will cover 10 by 8. works at about f/7; also single wide-angle landscape lens, No. 3 Voightlander, new series, covers 8½ by 6½; both good as new and give good results. What offers? —L. H. L., 65, Shooter's Hill Road, Blackheath, S.E.

Swift's 16 in. focus triple landscape lens, with iris, cost £5 5s., sell £3; approval; deposit. —Conybeare, Ingatesstone.

**Sets.**—Army and Navy Stores' quarter-plate camera, stand, three double backs, first class rapid rectilinear lens, Thornton-Pickard's instantaneous shutter, canvas case, six dishes, six plate boxes, all as good as new (cost over 105s.), 50s.; also 5 by 4 Optimus lens, almost new, £1. —Hildyard, 11, Moreton Gardens, London.

Quarter-plate mahogany camera, rapid rectilinear lens, folding tripod, drop shutter, double back, very cheap, 58s. 6d. —Presland, Claverham, Berwick, Sussex.

Good quarter-plate bellows camera, rack and pinion, new double slide, single lens, tripod, case, bargain, 16s.; sample print 3d. —Goodman, Carriage Works, Loughboro'.

Magnificent 10 by 8 camera, three slides, velvet-lined case, Raymont's patent, Ross' 14 in. rapid symmetrical, Ross' 9 in. portable symmetrical, Thornton shutter, brass bound, three fold stand and case, all new last November, cost over £30, price £22; also double blind Thornton shutter, 2 in., 15s.; also Chadwick's hand-camera, 12 slides, no lens, home-made quarter camera to use with slides (brass work alone cost 10s.), real leather case, the lot 65s. —Shaw, 5, Great Ancoats Street, Manchester.

Stereo camera, one double, one single slide, well matched lenses, splendid definition, £5 5s., excellent condition; deposit. —30, Stapleton Road, Bristol.

Rough 5 by 4 camera, changing back for 12 plates, three double slides, leather case, £4; Ross' whole-plate rapid symmetrical, £4 10s.; Dallmeyer W. A. landscape, whole plate, £3; Meagher whole-plate camera, three slides and stand, £4 10s.; two Wray's 5 by 4 R.R., paired by maker, £4; all as new; £18 the lot. —Rev. J. A. Lloyd, Mere Vicarage, Wilts.

**Sundries.**—Whole-plate Optimus burnisher, 21s.; whole-plate mahogany retouching desk, drawer and carriers, 15s.; both new. —17, Sedan Street, Walworth.

**Telescope.**—Optimus tourist telescope, three draws, 2½ in. object glass, cost £2 10s., price 25s. —Lennard, 29, Clarence Street, Preston.

**Tripod.**—Good oak tripod, suit quarter or half plate, bargain, 2s. 6d. —Goodman, Loughborough.

## WANTED.

**Cameras, etc.**—Wanted, quarter-plate camera, hand or stand, suitable for beginner, must be cheap. —10, West Street, Harwich, Essex.

Wanted, quarter-plate double extension Kinnear-shape bellows camera, with turntable and legs, two or more double slides, good maker, cheap for cash; approval; deposit. —W. Clare, Malvern Wells.

**Cameras, Lenses, etc.**—Whole-plate camera by good maker, also rapid rectilinear lens; letters only. —T. C. Hosking, 1, Baldwin Crescent, Camberwell.

**Enlarging Apparatus.**—Enlarging lantern, quarter-plate; approval; deposit. —S. Harris, Windsor Road, Aintree, Liverpool.

**Sundries.**—Wanted, small negative transparency or 8 by 6 enlargement of the common house. State price to Waters, Chemist, Amble.

**Bargains in Cameras and Sets.**—15 by 12 double extension camera, leather bellows, rising and falling front, wide-angle movement, fitted three double slides, as new, take £3 8s.; 12 by 10 camera, double extension leather bellows, wide-angle

movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole plate Underwood instant, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide, changing box, for 24 plates, also changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; half-plate 1892 Instantograph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; quarter-plate Underwood's instant, finest order, changing box for 12 ¼-plates, good lens, rotating stops, one slide, folding-stand and case, 35s.; 1891 Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Bargains in Hand Cameras.**—Swinden and Earp hand-cameras, carries 20 quarter-plates, fitted Taylor and Hobson's best rapid rectilinear lens, roller-blind shutters and case, as new, £6 15s.; Adams' Ideal hand-camera, carries twelve quarter-plates, finest rapid rectilinear lens, two finders, etc., as new, £5 17s. 6d.; Steinheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Optimus detective camera, by Perken, Son, and Rayment, Optimus rapid rectilinear lens, carries six ¼-plates, covered black leather, take £4 4s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 15s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, take 27s. 6d.; Griffiths' best quality hand-camera, carries six ¼-plates, two sunk finders, good lens, pneumatic shutter, take 30s., cost 42s.; quite new, all above are warranted as described. On view, City Sale and Exchange Rooms, 54, Lime Street, corner of Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description. —We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail. —City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus of every description bought, sold, or taken in exchange. Inspection invited.

**Bargains in Lenses.**—10 by 8 Lancaster's rectigraph lens, Silver Ring, iris stops, as new, £3 7s. 6d.; whole-plate portrait lens, rack focussing, Waterhouse stops, works f/6, take 68s.; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross' actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; whole-plate Suter No. 3, landscape rotating stops, about 12 in. focus, quite new, 37s. 6d., lowest; 8 by 6½ Ross' rapid symmetrical, Waterhouse stops, grand definition, as new, £4 12s. 6d.; half-plate Ross' portable symmetrical, rotating stops, 4 in. focus, finest order, 45s.; quarter-plate Continental wide angle rapid rectilinear, rotating stops, as new, 25s.; half-plate wide angle, by Morley and Cooper, rotating stops, as new, 27s. 6d.; half-plate wide angle, by Lancaster, 10s. 6d.; half-plate Ross' rapid symmetrical lens, as new, moveable hood, Waterhouse stops, take £3 17s. 6d.; Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d.; Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described. —On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

**IMPORTANT TO AMATEURS.**—Negatives skillfully Retouched. Printed in silver, gelatin-chloride, etc., and Enlarged. Also Developing, Copying, etc. —Terms strictly moderate. —Address, Wilfred Emery, 24, South Street, Baker Street, W.

# Have you seen the Latest Mounts?

It is not generally known that we manufacture every class of Photographic Mounts, and that many Presentation Pictures for Her Majesty the Queen and the Prince of Wales are mounted upon our Artistic Mounts.

## ASSORTED BOXES OF MOUNTS.

The Best Selection of Photographic Mounts ever placed in the Market.

No. 1 Box, containing 60 different Mounts from Midget to half-plate, 2s. 6d., postage 4½d. extra. No. 2 Box, containing 130 well-selected Mounts, 5s., postage 7½d. extra.

### Exhibition Gainsborough Mounts.

Arranged for 6 ¼-Plate Photos, also 6 Cabinets, 6 ½-Plates, 9 Cabinets, and 13 C. de V.'s.

THE CHEAPEST OXFORD LINE MOUNTS IN THE MARKET.

**OUR NEW ILLUSTRATED CATALOGUE**, containing prices, which can be "quickly" found for any Photo Mount required. The goods can be had through respectable Chemists and Photo Dealers, at prices stated therein, and when compared will be found lower than any others in the trade.

## HANNAM & COMPANY, Cardboard and Mount Factory,

Show Rooms and Warehouse:

25, SOHO SQUARE, LONDON, W.

Atlas Works,

GAINSBOROUGH.

# THE AUTOTYPE COMPANY, LONDON.

## AUTOTYPE DRY PLATES,

### Rapid and Instantaneous.

Perfectly Coated with a rich and highly Sensitive Emulsion. Popular prices. These Plates the Company can confidently recommend as equal to any brand in the market.

The following recent Testimonials can be seen at our Office:

"June 21st, 1892.

"I have recommended your plates to all my friends for outdoor work, as I find them by far the best. There is an entire absence of Halation."

"May 25th, 1892."

"I am very highly pleased with your plates; they develop up better than any first class plates I have tried yet. It is the Hydrokinone I develop with."

"June 21st, 1892.  
"I prefer your plates to any I have ever tried, being able to get much better contrast than on any other plates."

"May 30th, 1892.

"I find your plates are all a professional can desire."

"May 30th, 1892.

"I like your plates immensely, and when I get rid of present lot will use yours exclusively."

"Amateur Photographer" Monthly Competition, No. 40.—  
"PORTRAITURE AND FIGURE STUDY." Latest day, Sept. 19th.—  
Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, October 14th.)

SOME of our readers may be interested to know that Mr. Charles W. Hastings, formerly Editor of the AMATEUR PHOTOGRAPHER, from which position he retired at the end of last year, has sold his remaining interest in the above journal and in our other photographic publications, to our publishers, Messrs. Hazell, Watson, and Viney, Ltd., who for a long period have had the principal interest in them.

THE East London Photographic Society will hold their Second Annual Exhibition at the New Tabernacle, Old Street, London, E.C., on Tuesday, October 25th, 1892. The Council of the above society will appoint as adjudicators gentlemen of photographic repute, the names of whom will be announced in due course. The following are the classes for competition: Open Class (H), Amateur, General Photography: first prize, silver medal; second prize, bronze medal; third prize, certificate. Entrance fee, 1s., limited to one picture.

- Class A. Landscapes and river scenery.
- " B. Seascapes.
- " C. Groups and portraits.
- " D. Instantaneous (objects in motion).
- " E. Architecture.
- " F. Enlargements.
- " G. Novices' class limited to 12 months' knowledge.
- " H. Open class (amateur), general photography.
- " I. For pictures taken at outings.

All exhibits to be the entire work of the exhibitor.

Entry forms and full particulars may be had of the Hon. Sec., Mr. Wilkinson, 28, Shacklewell Lane, Kingsland, N.E., on receipt of stamped addressed envelope.

THERE are vacancies for a few new members in the Lantern Slide Exchange Club. The rules are:—

- (1) Subscription, 1s. per year.
- (2) One slide at least must be contributed per month; neglect incurs a fine of 6d.
- (3) Box must only be kept three days, and then forwarded by parcels post.
- (4) Every detail of slide must be given (printed slips are supplied for this purpose).
- (5) Slides will be divided amongst the members twice a year.

Mr. A. R. Dresser has kindly promised to criticise the slides every month. Further particulars may be had from A. J. Richardson, Hon. Sec., Summerville, Dore, Sheffield.

WE wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTO-

GRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

THE following are the judges' awards in the photographic section of the Royal Cornwall Polytechnic Society's Exhibition held at Falmouth:—First silver medals, R. H. Lord and W. M. Warneuke; second silver medals, W. J. Byrne, H. Tonkin, and F. H. Pickford; first bronze medals, W. H. Harrison, W. Scorer, J. Milman Brown, T. Protheroe, C. A. Roe, Major J. D. Lysaght, A. Nicholson and H. D. Arnott; second bronze medals, W. J. Anckorn, and A. W. Gottlieb; hon. mention, A. Guye and A. G. Tagliaferro.

THE Eastman Photographic Materials Company have named their gelatino-chloride printing-out paper the "Solio" paper.

## NOTES ON COLOUR.

### I.—LIGHT.

(Continued from page 115).

WORKING with such simple arrangements as described in our last article has considerable inconveniences; in the first place our beam of sunlight is very tantalising, it refuses to stay on the prism, and therefore we have either to move our prism continuously, or else arrange to keep our beam of sunlight stationary. The latter plan is more convenient, and for this purpose we use a heliostat, a mirror so connected with clockwork as to keep the beam of sunlight constantly reflected through the aperture in the shutter on to the prism.

In practice it is found convenient to make use of an instrument termed a spectroscope, which practically consists of a couple of telescopes with one or more prisms.

With the aid of a spectroscope, with three or six prisms we are enabled to obtain a spectrum of much greater length, and one in which, with one adjustment of the width of the slit, which should not be less than 1 mm., and of the various other parts, the colours are pure and free from any admixture of white light. On carefully examining the spectrum we find that it is not continuous, but is broken up by numerous transverse dark lines, which are called the fixed lines of the spectrum, and which are always found in a certain definite colour, and it is solely this point which interests us—so much so that it is usual to speak of a certain portion of the spectrum which it is wished to accurately define by saying that it is, *e.g.*, between D and E, or if we want to exactly locate the particular part of that colour or space, we say  $D \frac{1}{2} E$  or  $D \frac{1}{3} F$ , which means to say that the point in question is one-third of the distance from D between D and E. For this purpose these fixed lines were named according to the letters of the alphabet by Fraunhofer, who discovered these lines, Wollaston also doing so independently. In fig. 1 is given a representation of the spectrum obtained by the use of a spectroscope provided with a prism, the chief lines being distinguished by their respective letters placed above, the colours being placed below.

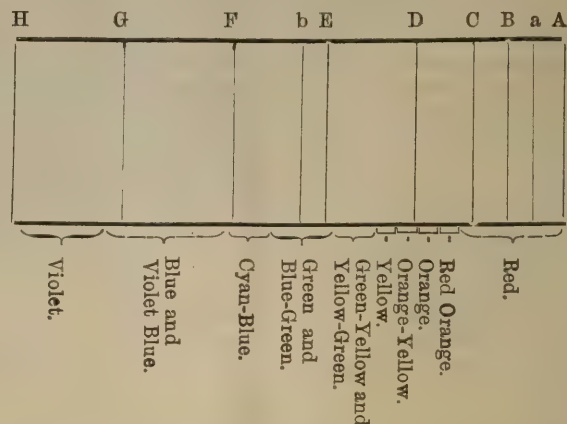

FIG. 1.

The colours of the spectrum, as we have seen, are arranged in a particular order, and this is found to be in the order of their wave length. To explain this term we must make a little digression, and for a simile return to waves on water. Most of us at some time or other have been on the sea, or by the sea, and have noticed the waves rolling, one after the other, sometimes in quick succession, with only a few feet between the highest points of their consecutive crests, in other cases many yards between; the two examples of quick and slow waves are well seen, the former with a rising tide, with a brisk breeze behind, and the latter, when, perhaps, a sea mist has hung over the water all the early morning, in the height of summer, and there is practically no wind, and we find frequently then a long, slow, almost oily wave, only recurring at a fairly long interval. Thus, as we note the quick and short waves, the length of the wave being taken as an imaginary straight line measured from crest to crest, and slow and long waves on the sea, so we find with light long and short waves; but it must not be supposed for one moment that the length of the waves of light are anything like the length of the waves of the sea. We have here to do with waves of almost infinitesimal length, yet these minute wave lengths have been accurately measured, and the results are expressed in "tenth metrets," or ten millionths of a millimetre, which is sometimes expressed as  $\frac{1}{10^{10}}$  metres, or as  $\mu\mu$ .

The following table gives the wave lengths of the principal Fraunhofer lines as determined by Angström in 1868:—

A = 7604.00	E = 5269.13
B = 6867.00	F = 4860.72
C = 6562.01	G = 4307.25
D <sub>1</sub> = 5895.00	H <sub>1</sub> = 3968.01
D <sub>2</sub> = 5889.04	H <sub>2</sub> = 3933.00

Other observers have fixed different values to these lines, but the above may be accepted as correct. It will thus be seen that in the spectrum the colours are arranged in the order of their wave length, beginning with the long waves of red, and passing gradually to the short waves of the violet. Unfortunately, we find one defect consequent on the use of a glass prism, and that is that it compresses the space occupied by the longer wave lengths and unduly elongates that occupied by the shorter. To avoid this defect it has been customary to use, instead of the prism of the spectroscope, a diffraction grating, which is a sheet of glass or metal ruled with an exceeding great number of fine parallel equidistant lines; thus Professor Rowland, of America, has ruled concave diffraction gratings with 43,000 lines to an inch without an appreciable periodic error of one-hundred-thousandth part of an inch; with these reflection or diffraction gratings a spectrum is obtained, which is called the normal spectrum, in distinction to the

prismatic spectrum, or that yielded by prisms, and in the normal spectrum the colours will be arranged in an equable manner with reference to their wave length.

The spectrum is supposed to be divided into 1,000 parts.

Hitherto we have considered only those colours which are distinctly visible to the eye, but if the room in which our spectrum is formed be well darkened, and we shut off the visible spectrum by receiving it on a piece of dead black paper, with very careful observation we can observe a continuation of the spectrum at each end, that beyond the red being a very deep red, or rather a chocolate, that beyond the violet a faint grey; the former are termed the infra-red, the latter the ultra-violet.

If we were considering the question of colour only, these invisible spectra would interest us but little; our subject being, however, colour and photography, these invisible rays, or, at least, one portion—the ultra-violet—are of great importance, and this will be treated of presently.

The existence of these invisible rays may be confirmed by two very simple experiments. Thus, taking the infra-red first, we can prove their existence by moving a thermopile and galvanometer from the violet to the red end of the spectrum; as the thermopile advances along the spectrum the needle of the galvanometer will be deflected from zero, its normal position, more and more, till we pass beyond the end of visible red, when it reaches a point of maximum deflection and then gradually goes back to its original position. The existence of the ultra-violet rays may be proved in a somewhat different manner. It is easiest proved by using a solution of sulphate of quinine in dilute sulphuric acid, and diluting with water, or else by using an alkaline solution of *æsculin*—an active principle obtained from the horse chestnut. Having made our solution, it should be placed in a thin, white glass vessel, such as an ordinary test tube, and entering our darkened room, let us see what happens if we hold the test tube in the various colours of the spectrum. In the red, it appears red; in the yellow, yellow; in the green, green; in the blue, however, our solution begins to appear a peculiar bright blue, which increases as we pass through the violet, and still continues

visible after we have left the violet and passed into the space where we suppose the ultra-violet rays to reside. Nor is this appearance visible only in the darkened room, but if the tube containing our solution is held in bright sunlight, against a piece of black velvet, and looked at, not through the peculiar blue shimmer, which is termed fluorescence, is plainly visible.

## Letters to the Editor.

### WASTE MATERIAL.

SIR.—Would it not be interesting know how much of the precious metals is annually used in connection with photography?

I expect it is a very large amount, and if we knew how much of that is wasted, *i.e.*, allowed to run into the sewers, we should be a trifle surprised. Can it be the cause of so many gold and silver fish? Occasionally I have an idea, and I am thinking that if a large number of us were to combine, and in some way or other to centralise this waste, it might be a case of "out of something, something came." Of course, the scheme would require some organisation, and these hints a lot of trimming (which I have no doubt they will get). I do not know that it would be altogether necessary to have pipes laid on to the under-part of your offices, for all old gold baths and silver washings to get to you, still I must think that if such an arrangement were carried out some big benefits would arise. For instance, if the amount, after all deductions for working expenses, should buy, say half a dozen first-class photographic outfits, these should be given to those deserving them, myself one of course, and to any other poor struggling, deserving, son of his ma.

Another year we could buy a life-boat, and name it "The Angel of the Artists of the Sun." There would be also all the paper cuttings. What a splendid pile! These, of course, could reach you in sacks, per Pickford and Co., or we could reduce them to ashes, and charter a special dust-cart for their conveyance. Again, photographic societies might help themselves. Each member should "save what he wastes," and lodge it where arranged, then when the *quantum sufficit* accumulated it should be sold, and with the proceeds some approved piece of apparatus should be purchased for the use and benefit of that particular society. If you think this idea can be successfully worked, and you require a really trustworthy collector to go the rounds of all the London and suburban amateurs, who would be advised through your columns, I can unhesitatingly recommend myself. All I should want at first would be a tricycle with a large tank attached, or perhaps a specially constructed pony-trap, after the style of a sliding body camera, mounted on two wheels, and with a large brass tap at the back, in shape like a photographic lens.

At first sight, the plan may appear the least bit wild; anyhow, I hope it is original.

H. S. LARGE.

\* \* \* \*

### EXPOSURE FOR INTERIORS.

SIR.—As your correspondent W. H. H. has questioned your advice regarding exposure for interiors, I hope he will not take it amiss if in turn I question his.

Like him, I have photographed a number of cathedral interiors, and if I had given anything like the exposures quoted, the results would, I fear, have been anything but first-class.

In the first place, the developer used by W. H. H. is generally admitted to be the worst possible for the purpose, as hydroquinone has a decided tendency towards hardness and lack of detail in the shadows. My experience is that a weak pyro-ammonia developer is the best, and that to secure first-class results a very full exposure must be given.

Using "Castle" plates and lens at *f/32*, I have never found an hour's exposure too much in the choir or nave of a cathedral—Peterborough perhaps excepted, as the stone is almost white.

The print of Exeter Cathedral, which is enclosed for your opinion, was taken on one of Edwards's instantaneous isochromatic films last June, in a first-rate light, with lens at *f/32*, and received an exposure of nearly 30 minutes.

These films are more than double the speed of the medium ones, but I think you will admit there is no great sign of over-exposure.

My advice would be to multiply W. H. H.'s exposures by three or four, to use a weak pyro developer, and to carefully back both plates and films.

It seems a great want your never having a monthly competition for the interior class. Could you not arrange to have one now and then?—Yours faithfully,  
J. G. P.

[The print sent is a very fine example of interior work, full of detail and great softness. On the other hand, our correspondent W. H. H. of last week also sent us some prints of almost equal merit. As the programme for our competitions is fixed for this year, we are unable to make any change, but would include interiors for our next programme.—EDITOR.]

### A TRIP TO CHICAGO.

SIR,—Your correspondent, Mr. C. J. Harris, asks (page 98) about the import duty on amateurs' photographic apparatus in America. So far as my own experience with apparatus purchased abroad on four different occasions goes, I may say that if his camera, etc., bear signs of usage abroad, and he swears that he has used them for twelve months, they will probably be admitted free of duty, but if they are new, he may be obliged to pay a duty, which in my case amounted to about eightpence on every shilling of prime cost. But I think in this case excursionists whose return tickets give prima facie evidence of their character as such, will not have duty to pay. I have been allowed to take American dry-plates, etc., into Canada upon giving the assurance that I was only a tourist, and should take them back into the States when used. One warning, however, I would give to all intending visitors to the Chicago Exhibition, and that is, to make as much of the journey as possible by Canadian lines, both of rail and steamer. The "gospel of hoggishness," of which Major MacKinley is the chief prophet, is bearing its natural fruit in the riots at the Carnegie Ironworks, and the strike of the railroad switchmen at Buffalo, and the articles in the papers, showing how eight hundred belated excursionists were held outside Buffalo from daybreak to noon, show what you may expect next year. If the railroad men use the opportunity afforded them by the Chicago Exhibition to enforce their claims for a full share in the railroad companies' profits, they will only be carrying out Major MacKinley's principles, but in doing so they will undoubtedly expose the foreign tourists to very great inconveniences. On the other hand, the Canadian Pacific Railroad Co. and the Grand Trunk Railroad Co., as well as the Allan, Dominion, Beaver, and other Canadian steamship lines will undoubtedly make special arrangements for the comfort of their customers and a good understanding with their work-people. I should advise those who come, to form clubs for mutual protection, and make all arrangements for transportation with the companies' agents in England. In this way they will certainly travel more cheaply and comfortably than as individuals. Much more than the custom-house duties, I should fear the vile smells, the bad water, the great heat, and enormous hotel charges of Chicago. I spent six months very cheaply and comfortably at the Philadelphia Exhibition of 1876—my average expenditure not exceeding three guineas a week, but the heat was sometimes 103° Fahrenheit in the shade, and many visitors were prostrated by it and by unwholesome food and drink. Naturally photographers will prefer to bring their own instruments, for the finest scenery they will pass is that of the voyage past Newfoundland and up the Saint Lawrence River, but to those who contemplate purchasing here, I would say that while lenses, dry-plates, and chemicals are far cheaper in Europe than here, the American cameras and all cabinet work are as good and as cheap as those of Europe. For tourist and hand work, for instance, I find a Blair camera (hawkeye or extension), with a Wray or Beck lens, better than any camera I could buy for the same money in England. Dry plates 4 by 5 inch, cost here on glass 65 cents or 2s. 8d., on Eastman or Blair film 75 cents or 3s., and on Carbutt celluloid film 80 cents or 3s. 4d. per dozen, and other sizes in proportion. I prefer the films because the glass is mostly very thick and seldom flawless, while in every dozen I find one or two plates which, though they may fit the spring-holders used here, are too irregularly cut for the book form of dark slide used in England.—Yours truly,  
JOHN FRETWELL.

## Reviews.

*Pictorial Selection in Photography.* By W. G. D. Price 7d.

The author has given us in this little pamphlet of twenty pages a very clearly written treatise on pictorial selection, and evidently fully understands his subject. Numerous illustrations are included, some of which certainly recall illustrations which have appeared in other works and in our pages. The pamphlet is well printed, and copies may be obtained from Mr. H. D. Gower, 16, Wandle Road, Croydon.

### COBALT TONING.

M. ALEXIS REDARES, in a communication to *La Photographie*, relates his experience in regard to cobalt-toning. He says, in place of cobalt depositing itself on albumenised paper in a metallic state it deposits brown oxide of cobalt, and the proofs obtained are of a reddish colour, and leave much to be desired. He used the following solutions:—

A.					
Water	...	...	...	...	1,000 cm. 3
Chloride of cobalt	...	...	...	...	10 gr.
B.					
Water	...	...	...	...	1,000 cm. 3
Acetate of lime	...	...	...	...	40 gr.

100 cm. 3 of A mixed with 130 cm. 3 of B, leaving this mixture three or four days before filtering. Test by sunflower paper to find if solution is acid or basic. If acid, add drops of a 10 per cent. solution of bicarbonate of lime. If basic, saturate with a 10 per cent. solution of hydrochloric acid. The bath should be absolutely neuter, otherwise it will not tone. From two to three days are required to tone by this process on ordinary paper. Fix with hyposulphite as usual.

M. Rédares has used in the bath acetate of lime in place of acetate of soda, which he finds has no reducing power on the salts of cobalt. He expresses hopes of perfecting the cobalt-toning, and regrets he cannot yet give a formula which will tone in a couple of hours.

A Giant Panoramic Camera of Moessard's pattern has been dispatched by Messrs. George Houghton and Sons, of 89, High Holborn, and was made for the Canadian Pacific Railway, and to take pictures 48 by 15 in. It is the largest camera of the kind constructed, and took eight months to make, and will cost about £100. The lens is a rapid rectilinear, 2½ in. in diameter, fixed focus, 20 in., working at about *f*/10, made by Hermagis, of Paris, and is valued at about £30. A stop with an oblong aperture is fixed in the lens. There are also the ordinary stops, the largest aperture being 2 in., the smallest ⅜ in. The camera is made of well-seasoned French walnut wood, unpolished, and with flush panels, and in packing up the sides and top fold over. The camera stands on tripod stand, which is 51 in. from the ground. The back of the camera is semi-circular in form, and the slides, of which there are three, are flexible, being made of card and cloth, fitted with celluloid and metal rims. Films, of course, are used. Wood clamps are supplied to hold the slides firm and flat whilst putting in films; also a strip of ground glass in case the fixed-focus may require adjusting. The front of the camera is of black indiarubber cloth. In the middle of front is fixed a metal support to hold the lens front, which can be moved in a semi-circular direction by a bar-lever on top of camera. Two lines are cut in the wood of camera top to mark the limits necessary to move lens in order to cover the whole of the film, which is exposed about ¼ in. at a time. This is arranged by means of a cone of blackened wood connected with the lever which moves the lens, the cone and lens thus always keeping in horizontal line, and moving simultaneously. The cone is 15 in. high, about 3½ in. broad near the lens, and is a slit of ½ in. broad near the film, thus allowing only a narrow strip of the film to be exposed at one time. The rise and fall of the lens is provided for by means of two extra wooden fronts, which are easily attachable. The camera is fixed to the tripod head, which is 15 in. diameter, by a central screw. There are also three other ordinary-shaped screws placed at equal distance in the tripod head, and working against a thin flat strip of metal fixed to the bottom of camera, which serve to adjust the level of camera. A small level is fixed on top of the camera. The panorama included is about 120 deg. The tripod is made of walnut, being 3½ in. wide, and the whole when packed in a case weighs about 1½ cwt., and measures 54 in. long by 34 in. high and 17 in. broad.

## General and Photographic Chemistry.—V.

By E. C. CONRAD, F.C.S.

### THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.—(Continued).

#### NITROGEN (N=14).

ONE litre at Stp. weighs 1.25 gram.

Oc.: In the air, of which it constitutes four-fifths by volume, it is given off in large quantities from subterranean sources. M.: It can be obtained from the air by several methods—(1) By burning a piece of phosphorus in a confined portion of air, all the oxygen will be withdrawn to form phosphorous pentoxide and the nitrogen will be left. (2) By passing a current of air over heated copper, the oxygen will form copper oxide, and the nitrogen can be collected. (3) A solution of cuprous chloride in hydrochloric acid absorbs oxygen from the air; Eq.:  $\text{Cu}_2\text{Cl}_2 + 2\text{HCl} + \text{O} = 2\text{CuCl}_2 + \text{H}_2\text{O}$  and 4N from the air. Nitrogen can also be prepared by passing chlorine gas through a strong solution of ammonia; the ammonia must be in excess to prevent the formation of an explosive compound. By heating a solution of ammonium nitrite; Eq.:  $\text{NH}_4\text{NO}_2 = 2\text{H}_2\text{O} + \text{N}_2$ . By heating a mixture of sodium nitrite and ammonium chloride; Eq.:  $\text{NH}_4\text{Cl} + \text{NaNO}_2 = \text{NaCl} + 2\text{H}_2\text{O} + \text{N}_2$ . P.: Pure nitrogen is a colourless, tasteless, inodorous gas very slightly soluble in water, 100 c.c. of which dissolve about 1.5 c.c. of the gas at ordinary temperatures. It is incombustible and a non-supporter of combustion. It is an inert body combining with very few elements directly. Although nitrogen is inhaled in large quantities at every inspiration, it is without any action on the animal economy, but is most important in regulating the supply of oxygen to living organisations.

THE ATMOSPHERE.—The gaseous envelope of the air that surrounds us is a mechanical mixture, and not a chemical compound. For although the chief constituents are almost quite constant in their relative amounts yet they are not in combination, their perfect mixture being due to the property of gaseous diffusion, by which a mixture of gasses become uniformly diffused over any given space irrespective of their relative specific gravities.

Proportion of Oxygen and Nitrogen in the Air.—The proportions are for 100 parts—

	By Weight.	By Volume.
Oxygen	23.00	20.83
Nitrogen	77.00	79.17

Although oxygen is always being withdrawn from the air by respiration, combustion, and oxidation, yet the amount contained is so vast that, without reckoning any cases of increase (some of which may be mentioned in the course of this work), it would take many centuries to affect the relative proportion by more than the merest fraction.

Other Substances in Air.—Besides the two gases mentioned, the air contains quantities of several other substances, of which the most important are—

(1) Ozone in air. The amount of the allotropic modification of oxygen in air is relatively very small, being in country air about 1 volume in 700,000, increasing in sea air, and much less in the air of towns. Its principal use appears to be the oxidation of putrid organic matter.

(2) Aqueous vapour in air. Water suspended in a state of vapour. Air is never quite dry, but the amount of water contained is constantly varying, depending on the temperature, direction of the wind, etc. All bodies of water give off vapour under the heat of the sun, and atmospheric changes cause the excess to be thrown down as rain, dew, etc. Water vapour is no doubt one of the most important

agents in increasing the heat of the air, by retarding the passage of the heat rays from the sun, and to much greater extent by the large amount of latent heat that becomes manifest on its condensation.

(3) Carbon dioxide in air. Carbon dioxide is always found in the air, and is continually being produced by the combustion of carbon compounds and to a larger extent from subterranean sources. It is, however, being continually decomposed by the action of the green colouring matter (chlorophyll) of plants in sunlight, the carbon being retained by the plant and the oxygen returned to the air. It has been observed that a square metre of leaf surface can decompose a litre of carbon dioxide in an hour of bright sunlight. The amount of this gas contained in the air varies from about 3 to 10 parts in 10,000 parts of air, but as the S.G. of the gas is high and therefore its diffusive power low, it may increase to a very large extent in confined situations. The air of a room containing only 0.1 per cent. of carbon dioxide is unfit for continual respiration, hence the importance of ventilation. Although the relative proportion of carbon dioxide in the air may appear small, the actual amount contained in our atmosphere has been calculated at 3,000 billion kilos.

(4) Ammonia and nitric acid in air. The air always contains ammonia and nitric acid in variable quantities and in relatively small amounts. It is from these compounds that plants obtain their nitrogen; they do not appear to be able to draw it direct from the air.

Average Composition of Air.—The following table gives the average approximate composition of ten thousand volumes of pure atmospheric air.

Oxygen	...	...	...	...	2065.94
Nitrogen	...	...	...	...	7790.60
Carbon dioxide	...	...	...	...	3.36
Ammonia	...	...	...	...	0.08
Ozone	...	...	...	...	0.015
Nitric acid	...	...	...	...	0.005
Aqueous vapour	...	...	...	...	140.000
					10,000.000

Besides the above, air often contains many accidental impurities.

Extent of the Air.—It is probable that the atmosphere, in an exceedingly rarified condition, extends through space, and that the condensation round us is caused by the earth's attraction. The portion so affected extends about forty-five miles from the level of the sea, but rapidly decreases in density.

Pressure and Weight of the Air.—The pressure that the air exerts is measured by the barometer, and is about 14.73 lb. on every square inch of surface. The weight of a litre of dry air at Stp. is 1.293 gram.

Ventilation.—It is of great importance to health that the air in rooms and houses should be kept as pure as possible by a constant circulation of the air, and this is especially necessary in dark-rooms, as the impurities in the air affect chemical substances, and temperature chemical operations.

We may point out that it is practically useless to provide a way of escape for the impure air, unless provision is also made for the entrance of pure air and a current produced. A draught is not desirable and quite unnecessary, but the air must circulate.

(To be continued)

Dark Room.—The Misses Abrahams, Pension Anglaise, Heidelberg, Germany, have now a perfectly fitted up dark-room, with washing tank, etc., for changing or developing plates. As there are plenty of good subjects about Heidelberg, this will be useful information for amateurs bent on a tour in Germany.

## The New Concentric Lens.

THE construction of a lens to give a "positive" focus or that caused by rays of convergence has hitherto been obtained by the radius of convexity of one refracting surface being shorter than the concave one. As an illustration of this, take a simple lens of the form shown in the diagram (fig. 1). If the meniscus form of this were to be altered by making the concave surface deeper, the lens would have no convergent focus at all, the rays would become divergent, and the result would be negative. Supposing this lens to be a compound made up of crown and flint glass, the latter having the greater refractive power, it will still be observed that the sum of all the positive curves is deeper than the sum of the negative radii. This form of construction is reversed in the "concentric," in which lens the convex surface has a longer radius than the concave, the diagram of which would at first sight lead

FIG. 1.

one to expect a negative focus without any image; but this is not the case, for, by the selection of a suitable crown glass for the positive element, of higher refraction than the flint of the negative element, the rays are caused to converge, and by the special effect of refraction on the oblique pencils the lens, although of this peculiar form, gives a real image free from distortion on an absolutely flat field extending over a circle of about 75 degs., the margin being as sharply defined as the centre; and, moreover, the whole is practically as equally illuminated as the theoretical limit will permit.

Every simple lens is represented by a system of prisms, whose angles are formed by the tangents of the radii. If two prisms or lenses are cemented together to form an achromatic prism, or lens, the angles of the two components are in a certain relative proportion, determined by the ratio of refraction and dispersion of the glass employed. When rays pass through such a lens, achromatic both at centre and margin, these angles may then be

FIG. 2.

greater, yet the relative ratio of both must be the same as those at the centre, for, if they differ in ratio, the marginal pencils will not be achromatic, and will be deviated in undue proportion, and besides colour, will cause optical distortion. Taking an ordinary compound meniscus lens, whose curves are represented in the diagram (fig. 2), we find that the tangents of the three curves are parallel at the centre, so that there is no distortion or deviation of the direct incident pencils; but, as we leave the centre, we find that the tangents of the first and second curves approach

one another, forming a wedge or prism, and the tangents of the second and third curves form a similar prism of smaller angle and in the reverse direction. This implies a greater power of the crown lens at the margin; and, as this has positive aberration, the image produced by the margin of the achromat must be smaller than the central image, and hence barrel-shaped distortion and coloured fringes are produced. In the diagram (fig. 3) representing the "concentric" lens, it is evident, on consideration, that on account of concentricity the two tangents, which, with the central plane, form the prisms, are always parallel, and the angles formed in constant ratio. Such an achromat will there-

FIG. 3.

fore produce neither general distortion nor distortion of the coloured images.

The field of the concentric lens is practically illuminated equally all over. In all lenses the diaphragm reduces the amount of light in proportion to the deviation of the oblique cone of rays from the central cone (fig. 4). This diminution of light towards the margin of the field is small, however, when compared to that

FIG. 4.

due to astigmatism and longitudinal spherical aberration in all ordinary lenses. The elliptical appearance of the diaphragm, caused by the oblique direction in which it is viewed, is exaggerated by the distortion in ordinary lenses, which have the property of diminishing objects in the horizontal diameter, whereas in the "concentric" lens, the diaphragm retains its proper shape until the light has nearly vanished. This is the effect of the opposite refraction due to the negative meniscus form having a positive focus, and which tends to open out—so to speak—the diaphragm to its normal circular form. An ordinary lens bringing its central rays to a sharp focus may be so constructed as to do so marginally also, but only on a curved field; a flat field being alone obtainable with such a lens by undue lengthening of the marginal pencils, resulting in astigmatism at the expense of definition. The rays do not actually meet in one point, so that the major portion is lost; or worse, they only assist to obliterate the sharpness of the actual working rays. In the "concentric," however, the whole pencil of rays go to form the image equally at the margin as at the centre.

Theoretically, a lens has no depth of focus; or, to speak more correctly, no depth of definition, for—optically—focus is a point. At the focal point the sharpest definition is obtained, but on each side there is a certain amount until the aberration becomes so

great as to be perceptible. Ordinary lenses which come to focus sharp only in the centre of the field, with vanishing distinctness towards the margin, are said to possess a certain depth of definition; but this is alone true for the centre, the remainder of the field being only a compromise for definition at all. In the "concentric," however, we start with sharp and equal definition all over the field, due to its novel system of construction; and thus the definition of all objects situated equidistant from the principal focussed object is equalised. Also, as there is no distortion or deviation of any portion of the cone of rays they may be said to cling closer together for a longer distance on each side of the point of true focus. The "concentric," therefore, more nearly yields the theoretical amount of depth of definition (regulated more or less by aperture) than any other lens, and consequently may be said to possess greater depth of focus or definition over the entire field.

In practice it is found that the "concentric" lens is considerably more rapid than other lenses of equal aperture and focus. By referring back to the diagram (fig. 3), shown to illustrate the loss of rays from spherical aberration and distortion, it is apparent that the whole cone being brought to a focus in the "concentric" without distortion, the "concentric" consequently works quicker than lenses in which a portion of the rays only is used, and where the non-focussing rays merely interfere by throwing useless light into the shadows.

Having now drawn attention to some of the chief differences between the "concentric" and other lenses, it will be desirable

FIG. 5.

before proceeding to examine and compare these lenses optically, to explain the principle upon which the testing apparatus is constructed. We use a stand to carry a photographic lens in direct line between a stationary lamp and a concentric and aplanatic magnifier; the adjustments attached are to alter the distances between the positions for convenience of focussing. Having by this means examined the central pencil, the magnifier at the back is moved aside in a line towards the margin of the field, and a movable lamp placed at a distance is traversed on a plane parallel and at the same level as that in which the magnifier is moved, and which corresponds to the surface of the ground glass of a camera; the magnifier is moved sideways until the lamp and attached dial are visible, the angle subtended then being equal to that of the opposite side. This represents the view angle, or, as the case may be, the diagonal of covering at that particular angle. The two diagrams herewith

(figs. 5 and 6) represent the principle upon which this method of testing is based, and it will be found that all that has been stated in connection with the "concentric" lens is optically correct, both when taken by itself and in comparison with other lenses. It should be mentioned that the magnifier being of the form of a sphere with concentric surfaces, the focal distance from

FIG. 6.

the centre is the same at all angles of obliquity, so that it requires no axial adjustment to meet the line of an oblique ray.

The above paper by Dr. Schroeder, the eminent optician, was read by Mr. Heyburn before the P.S.G.B., and the following is an abstract from the discussion which followed:—

Mr. Stuart said they claimed that the lens would give absolutely straight lines, used as a single lens, because the Gauss points were exactly in the centre, the diaphragm practically bisecting them. Supposing one of the combinations of a symmetrical lens were taken and used as a single lens the diaphragm would have to be pulled out considerably or the distortion would be very great. With the concentric, however, one of the combinations could be unscrewed and the other used without any alteration in the position of the diaphragm, and no distortion whatever would be produced. It might be used for copying maps, and, indeed, had already been so used.

Mr. Debenham said he had always stoutly maintained—and until he saw it demonstrated to the contrary he should continue to do so—that no lens was superior to any other lens in depth of focus. He supposed anyone would admit that with a lens giving good marginal definition the screen or the object might be moved for a certain distance and still show a certain amount of definition, but he should call that simply better marginal definition—that, he thought, was a better description of the characteristic. Further, the paper spoke of the concentric lens being quicker than other lenses, because where the rays were not brought perfectly to a focus some were lost by spherical aberration. That was only equivalent to saying that when a thing was perfectly focussed it was quicker than when it was out of focus, because whether there was spherical aberration or confusion by being a little out of focus came to the same thing. Of course there was less concentration of the light, but when the dispersion of the light surrounding it did not produce the effect of being less exposed; a picture was not found to be under-exposed in the unsharp parts more than in the sharp points. He thought the claim for rapidity in this respect was a mistake. With regard to the last diagram (fig. 6), showing the nearer points which were said to be distorted, he thought it altogether a mistake to call that distortion. It would be the same absolutely with this lens as with any other in viewing objects in that form. If they were arranged in a semicircle towards the lens they would be repre-

sented, by this or any other lens, large towards the margin, and smaller towards the centre, and that was not distortion, but simply the perspective of near-plane objects. He expressed his regret that these claims, which he regarded as mistaken and erroneous, should be made in respect of such a fine instrument as the concentric lens undoubtedly was. He had seen the lens and examined the definition and flatness of field, and thought it was a great additional power to the photographer; and in all cases where rapidity greater than No. 16 uniform system was not required, it seemed to him that it would be more useful than probably any lens that had preceded it, at all events where a widish angle was required. It was therefore much to his regret that these claims should have been made in connection with such a splendid instrument.

Mr. Stuart thanked Mr. Debenham for his complimentary remarks, but could not agree with what he had said about the rapidity of the concentric lens not being more than that of another lens of the same aperture and focus, for the reasons given by Dr. Schroeder. It must be apparent to anyone that where the rays come to a point there must be more intensity—that could be illustrated with a common burning-glass. There was another reason: less secondary spectrum in the glasses used than in the flints and crowns usually employed.

Mr. Debenham: Except the apochromatics.

Mr. Stuart: Even they could not be so colourless as lenses constructed of practically two crowns as in the case of the concentric. The glasses used were so crystalline that if, say, a symmetrical and a concentric were examined side by side on a piece of white paper, the difference of colour could be seen at once. He hoped Mr. Debenham would not say that colour in dense glass was not detrimental to the rapidity of a lens. In the construction of telescopes, when using a glass of a specific gravity of, say, 3.65, he had found that one maker's glass would take about 10 per cent. off the light of another maker's. He did not say there would be that difference in photographic lenses, but it was certainly appreciable, and he thought it a sufficient reason for claiming extra rapidity for the concentric. But he would take the question practically. Like Mr. Debenham, he was himself an old hand at the camera, and he had had the lenses tried side by side on the same plate, and the concentric lens gave an intense image, while the other was much under-exposed. He would go so far as to say that there was practically a difference in rapidity of 25 per cent. in favour of the concentric over any other lens, no doubt due to the absence of colour and secondary spectrum in the glasses used, the extreme intensity and sharpness at which the rays were brought to a focus at all parts of the image; and the fact that the lenses are exceedingly thin, each combination having practically an equal thickness at all parts, which is not the case with other lenses.

Mr. Debenham said on the question of speed two points had been made. One referred to colour, and it had been put upon him that he was to quarrel with opticians, and tell them that the colour of a lens had nothing to do with speed. He did not speak about colour, nor did the paper; he only spoke about what the paper mentioned. The introduction of the question of colour was a new thing, and it was not fair to say that he had suggested that colour made no difference. He would, however, say this—that the difference between the colour of such lenses as Mr. Stuart had been sending out for many years—the rapid symmetricals—and the most colourless glass that could be had, was not very great. The rapid symmetricals had not got deep yellow or green glass, the colour was very slight, as he thought Mr. Stuart would agree.

Mr. Stuart quite acquitted Mr. Debenham of bringing up the colour question, but he had asked for a reason why the concentric was more rapid than another lens. Dr. Schroeder did not go into the matter in the paper, but on a previous occasion he had given that as one of the reasons. As to the assertion that the rapid symmetrical had not more colour than the new lens, that could easily be tested by putting them side by side on a piece of white paper.

Mr. Debenham said the second point to which he desired to call attention was that of speed, owing to the concentration of the rays absolutely at one focal point. He thought anyone must see that if that was so—if that made a lens more rapid—the mere putting the plates a little out of focus would destroy rapidity, whereas that was not the case; a lens did not have a less rapid effect if out of focus. He wished to protest against the assumption that the slight amount of spherical aberration in the ordi-

nary lenses caused a loss of rapidity on account of the light not being brought all absolutely to one plane, because although the light was not absolutely focussed in one plane, it was present.

The Chairman said the light was all there, but not on the part of the plate where it was wanted.

Mr. Debenham said it was so close to it that it was only very slightly out of focus, and they did not find a picture very slightly out of focus any less exposed than one which was perfectly focussed.

Mr. Stuart said he was quite ready to put the point to the test in the camera.

## The Colour Screen in Landscape Photography.\*

BY CHARLES L. MITCHELL, M.D.

THE value and use of orthochromatised emulsions in landscape photography is now fully recognised, but as yet there still appears to be considerable difference of opinion in regard to the necessity of the co-incident employment of the colour screen. It is stated by many of the manufacturers who at present supply the market with iso or ortho chromatic plates, that the use of this valuable adjunct is by no means necessary, and that equally good results can be obtained without it. Having, during the past two years, made extended trials for landscape purposes of orthochromatised emulsions, coated on both glass and celluloid films, and during these experiments made frequent use of the colour screen, a few notes on the principles and methods of its employment may perhaps be of interest. The class of subjects selected was almost exclusively landscapes, and the large majority extended landscapes in the mountainous regions of Switzerland, Norway, and Northern Italy, involving distances ranging from ten to one hundred miles. The first year the colour screen was used sparingly, but the results obtained with it were so satisfactory that in the following year it was used whenever possible, and the success attending its use was so marked, and the quality of the work so far superior to the portion in which the screen was omitted, that I now am fully convinced that the colour-screen is an indispensable adjunct for any extended or comprehensive landscape work. The reasons for this opinion are not hard to find. It is a well-known fact that when an open landscape is photographed on an ordinary gelatine emulsion, two serious difficulties are always encountered. These difficulties bear such a relation to each other that the means employed to prevent the one always increase the evil effects of the other. I allude to the difficulty of obtaining even and harmonious exposures for both near foreground and extreme distance. The rapidly vibrating blue rays coming from the more distant portions of the landscape, produce in an extremely short time a very powerful reducing effect upon the emulsionised silver salts, and that long before the more slowly vibrating rays coming from the nearer and generally darker foreground have had time to properly act on the plate. The consequence is that when proper definition, detail, and colour value have been obtained in the foreground, the distance has been so over-exposed as to solarise to a greater or less degree that portion of the image. On the other hand, should the exposure be so shortened in time as to obtain proper values for the distance, the foreground is so hopelessly under-exposed as to be but an unmeaning smear of black, devoid of all detail.

All kinds of devices have been suggested for remedying these difficulties. Sky shades, shutters having apertures of different shapes fancied to diminish to a certain degree the exposure of the sky and distance, etc., etc., have at different times been suggested, but none of these have proved of sufficient value to become popular.

The difficulties, as above noted, are particularly noticeable in the case of Alpine landscapes. Here there is often a foreground of rocks and dark pines, abounding in dark greens and browns, and opposed to it a distance composed of brilliant snow-white peaks and glaciers, standing out against a deep blue sky, varied, perhaps, with floating clouds. With an ordinary emulsion it is almost impossible to render properly such a landscape, as the foreground will be under-timed and lacking in detail, or else the peaks and sky will be so over-exposed or "burnt out" on the negative as to render the demarcation line between snow and sky almost indistinguishable. When, however, certain colouring agents are added to the ordinary emulsion, as is done in the process of orthochromatising, an entirely new condition of affairs is brought about. I will not attempt to explain this in detail, for it has and will be done by much more able and qualified hands than mine. Suffice it to say, briefly, that while the emulsion is now in its altered character a little less sensitive to the action of the blue rays of the spectrum, it is more sensitive to the yellow, green, and red rays coming from the opposite end of the

\* Read at the Photographic Convention.

spectrum. A plate of this character, when exposed to the same alpine landscape as previously tried, would exhibit much more detail in the foreground, and the distance would be in much better tone. But although the sensitiveness of the plate, as orthochromatised, is of a much less degree as far as the blue rays are concerned, they are so powerful that they still act too rapidly on the emulsion, and it is desirable to limit still more their effect. This is accomplished by the colour screen. A suitable coloured medium, in this case yellow, is interposed between the object and the sensitised plate. This medium intercepts the passage of the blue rays to a certain extent, or diminishes the rapidity of their vibrations, and while prolonging thus the exposure allows the reds, greens, yellows, etc., to pass through without hindrance, and impress themselves fully upon the plate. The resulting image will now represent in much more accurate colour tone, as expressed in black and white, the different values of the landscape, giving full detail and softness to foreground and showing in the distance white peaks against a darker sky.

For purposes of landscape photography the colour screen employed should generally be of a light yellow shade, except in some special few instances, when to obtain particular effects in a landscape, coloured screens of more or less of a red or reddish orange may be found to be desirable.

From this brief explanation the principles which govern the employment of the colour screen may be made apparent, and on its very face the theory of its action would seem to be correct and of sound value. And I unhesitatingly assert that when the colour screen is *properly* used, the results will, in every instance, bear out the sound principles of the theory—landscapes when, while full justice is given to atmosphere, the distant ranges of hills are as clearly defined as they would be to the eye; water which looks like water and not an expanse of snow; foliage and verdure which show the varied shades of greens with which nature bedecks herself; or the varied tints in an autumn landscape, and clouds of white or pale grey floating on a darker sky, as we see them daily in the heavens. But a colour screen should be used with judgment, as should every other photographic adjunct, if good results are to be secured. Not for every subject, or for instantaneous work, or generally for objects close at hand, but for the special work for which its usefulness has been explained. Let us for a moment consider this and its practical features a little more in detail.

The first point to be considered is the colour screen itself. This should be of glass, perfectly flatted and ground to a true surface, or else it will produce such an amount of distortion as to render it totally unfit for use. In England, I have been informed, one or two firms offer for sale colour screens made of yellow pot glass ground and polished to a true surface. The only one of these I have been able to see was of so light a colour, and that more of a brown than a yellow, that I should feel afraid to use it. The quality of others may be better. It is very easy, however, for any photographer to prepare his own screens, and of whatever colour he may desire, by a process which I shall now describe.

Procure plate-glass, thin, perfectly flat, ground, and free from all striæ or bubble. The thin plate-glass that is frequently used for making colour cells and animalculæ tanks for the gas microscope will be found to be excellent for this purpose. After being cut in small squares of the size desired ( $2\frac{1}{2}$  by  $2\frac{1}{2}$ , and  $3\frac{1}{2}$  by  $3\frac{1}{2}$ , I have found answer nearly every purpose), a square should be flowed on one side, in the same manner as when coating a plate with collodion, with a solution of the colouring agent in amyl-acetate collodion. The colouring agent may be either "aurine" for orange red, or any other colouring matter desired, provided it is soluble in the varnish. For the yellow screen I am in the habit of using an aniline dye, called "golden yellow," in the proportion of from five to eight grains of the dye to the fluid ounce of varnish, according to the depth of tint desired. It is permanent, does not fade to any extent, and gives a rich lemon-yellow screen. The amyl-acetate collodion, now extensively used in the United States for the purpose of lacquering gas fixtures and brass work of all kinds, is known in trade by a number of different fictitious names, such as "Enameline," etc., etc. It is simply a solution of soluble nitro-cellulose in mixtures of amyl-acetate, ether, petroleum benzine, and alcohol, mixed in varying proportions. It can be easily prepared on a small scale by cleaning off the emulsion from a spoiled celluloid film, cutting the film up in small strips (soaking them well in strong alcohol to remove the camphor), and placing these in a bottle with a mixture of one part amyl-acetate, one part petroleum benzine, three parts alcohol, and three parts ether, all by measure. The celluloid swells up and dissolves rather slowly, hence the bottle containing the mixture should be well shaken at intervals for several days. A better collodion is made, however, by dissolving good nitro-cellulose in the above mixture. When the celluloid is all dissolved, the liquid should be filtered through a little absorbent cotton to remove any loose flecks of dirt. This varnish gives a tough film, clear and free from transversed striæ, and is also an excellent material for varnishing glass negatives or positives, being perfectly waterproof. To

resume, the glass square, after having been coated with the coloured varnish, is allowed to "set" for a few moments, and then placed aside on a flat surface until the varnish is perfectly hard and dry. Care must be taken to keep it covered while drying, so as to avoid dust and dirt settling on it. The coated plate is now placed on a level surface, film upward and sufficient pure Canada balsam (white and free from dirt) poured on the plate to make a pool in the middle of the plate of about one-fourth of its area. A fresh, clean glass square of the same size is next taken, and gently lowered on the balsam and plate in the same manner that a cover glass is placed on a microscopic object, and then a gentle and even pressure applied until all air is forced out, and the two glass surfaces are cemented together with the balsam, and are in uniform contact. The cemented plates are now laid aside on a flat surface, and allowed to remain several weeks undisturbed until the balsam has thoroughly hardened. Then the edges are cleaned off, the exuded balsam being removed with a little benzine or benzole, and the edges bound with some strips of lantern slide paper. This colour screen can be placed either before or behind the lens. If before, a special hood for each lens must be made to hold it. I, therefore, prefer to use it *behind* the lens, on the inside of the lens board, when it can be placed or removed in a few seconds. This can easily be arranged with two small brass or wooden cleats, secured down on the inside face of the lens board, and adjusted so that the colour screen can slide between them.

The next item is the subject. It is hardly necessary to say that moving objects and all instantaneous work are entirely beyond the scope of the colour screen, owing to the length of exposure required. Moving clouds can often be satisfactorily photographed when the motion is slow, and the exposure made with the full aperture of the lens, from half to two seconds being generally sufficient. Large masses of cumulus clouds, and also the lighter and more graceful forms of the cirrus, can be made, when at rest, to repeat themselves on the photographic plate with rare fidelity by the aid of the colour screen. There are many days of the year when these remain almost quiescent in the sky, and, as no great stopping down of the lens is needed, a large aperture and short exposure will yield excellent results.

For ordinary landscape work in close proximity to the subject the use of the colour screen is unnecessary, unless some special conditions of colour exist. Still life, fruit and flower subjects, however, are especially fruitful fields for the colour screen in conjunction with the orthochromatic plate. Here time is of no importance, absolute sharpness and fidelity of detail can be secured by stopping down the lens, and, with a full exposure, every feature of the object will be reproduced. The principal use of the colour screen in landscape photography, however, is in field work, especially where extended country, and often extreme distance are concerned. Here the colour screen is an *absolute necessity* in order to secure uniform and satisfactory results. I have photographs in my collection taken from the summit of the Furca Pass in Switzerland, where, while the foreground is harmonious and full of detail, the Alps of the Mont Blanc and Monte Rosa group are distinctly visible, although at least sixty miles distant. I have also noticed the use of the colour screen, when photographing in both Switzerland and Norway, has given much more brilliancy to the dull monotone so often noticed in the photographic rendition of long stretches of bare mountain side, it seeming to differentiate and accentuate the different tones of browns dark grey, and greens so prominent in such landscapes. In fact, I have grown to rely so much upon the colour screen in photographing these extended views, that I fear no landscape, no matter how extended, provided it is properly lighted, and I think I can show as satisfactory results for such subjects as it is possible to compress into the limits of a small photographic plate.

A word may also be said just here in favour of the use of celluloid films. Glass is as yet undoubtedly the most perfect medium of support for the photographic emulsion. But it is heavy, liable to break, and for distant landscape work apt to show halation. This latter, it is true, can greatly be prevented by backing the plate, but it is a tedious, dirty process, and involves infinite trouble. Celluloid, as now prepared in the United States, is rapidly taking the place of glass for tourists' work. It is now manufactured almost free from defects, and is so light and portable that a gross of 8 by 10 size will take up no more room and weigh no more than one dozen of the same size of glass plates. It cannot be broken, and, moreover, is almost entirely free from halation, owing to the thinness of the film and the consequent absence of reflecting surfaces. To illustrate its advantages, I may say that last summer I took a three months' trip through Norway, carrying with me, in a small Norwegian trunk, together with my clothing, sufficient material for six hundred 8 by 10 exposures. The weight of these films was about thirty pounds; the same amount of glass plates would have weighed over four hundred pounds—an almost insurmountable burden, unless one travelled with a baggage train.

It remains to say a few words concerning exposure and development. Exposures for orthochromatic plates should *always* be fully timed to secure soft and harmonious negatives. An under-exposed orthochromatic plate or film is much more inclined to fog on development, and is much more harsh and lacking in detail than an ordinary plate of the same speed would be if subject to the same conditions. On the other hand, the orthochromatic plate, and even more so the film, will bear an amount of over-timing which would simply be ruinous to an ordinary plate. When a colour screen is used the exposure should be prolonged eight or ten times, and my friend Mr. F. E. Ives, who is world celebrated for his researches in colour photography, has assured me that twenty times is none too much. I have no doubt some advocates of rapid exposures will be shocked by this statement, but when we consider the retarding effect of the colour screen, the amount of "leeway" in exposure is in consequence immensely extended. In all such work plenty of time in exposure is necessary to obtain full detail. The distance will take care of itself, so will the clouds, and unless there is a brisk wind blowing they will show up all right in the negative. Furthermore, in overcast and cloudy weather, exposures on orthochromatic emulsions, either with or without a colour screen, must be greatly lengthened, much more so than for ordinary emulsions under the same circumstances. For instance, if I gave two or three times the exposure (using an ordinary plate) on an overcast day that I would on a bright, clear day, for an orthochromatic plate (using no colour screen) I should give from *four to eight* times the exposure, and if I did not do so, I should get an under-timed plate. If a colour screen is used in addition, the exposure should be increased proportionately as previously mentioned. Most of my failures with the colour screen and orthochromatic film have been from this cause—under-timing on cloudy days. There seems to be, under these circumstances, an absence of certain light rays in the atmosphere (yellow perhaps) which ordinarily affect more quickly the orthochromatic emulsion. After I discovered this I have frequently, after making an exposure, the time of which I had judged should be ample, made a duplicate exposure, in which for purposes of experiment I doubled the exposure, and almost invariably the longer-timed negative came out the best.

Finally, a word or two may be said regarding the development of the exposed plate or film. The developer used must depend largely upon the purposes for which the negative is to be used. If for bromides, lantern-slides, or transparencies, my preference is for the mixed developer of eikonogen and hydroquinone, it giving negatives possessing the full detail and quick printing qualities especially requisite. For platinotype, plain silver, and kalotype, I am growing to believe that pyro gives perhaps better results. The steel or blue-grey image produced by the mixed developer gives a density which seems greater than in fact it really is, and in printing processes which tend to diminish contrast it will not give as brilliant and "plucky" a print as will the slightly yellowed pyro-developed negative.

## Toning Gelatino-Chloride Paper.

HAVING had numerous enquiries on the subject of toning the Ilford P.O.P., we approached Mr. John Howson with the idea of obtaining from him his views on this subject, which he embodies in the following notes:—

"The use of this paper is spreading so rapidly and so widely that we need not be surprised at the small crop of queries as to failures in its use, inevitable in any new or partly new process. These failures are for the most part in the toning, and, after more than twelve months' experience, I may be in a position to point out in a few sentences the cause of them.

"For the most part they are thus described:—

"(1) Slowness of toning, an hour being sometimes necessary to obtain any approach to complete toning, the result being poor and faded-looking, and is in time accompanied by the symptoms mentioned in the second kind of failures.

"(2) Yellowish-pink stains in the half-tones, and more especially round the edges of vignettes.

"An apparent toning which disappears in the fixing bath, and leaves a sickly yellowish-red print.

"Now I venture to assert most emphatically that all these three failures are due to the several stages of one cause, viz., the lack of gold; and I have proved the truth of this assertion by actual tests, which have produced the several defective results just as I wanted them.

"It may be premised here that gelatine paper requires considerably more gold than albumen paper did, and this may be taken as an enormous advantage in regard to the question of permanency; for the more gold, within reason, that is deposited on a print the more

stable will be that print, and the more certain to withstand any injurious influences that it may meet with in its after life.

"I know from much experience that the Ilford P.O.P. formula, containing 2 grains gold chloride, 30 grains sulphocyanide, and 16 ounces of water, will tone readily and perfectly one sheet of Ilford paper, but that the bath will then be practically exhausted. In some cases where the prints have a large proportion of heavy shadows, this bath will need an addition of a little gold to complete the toning within a reasonable time. *I would here say that experience has modified our first opinion on this point of addition of gold, and that no injurious action or result is likely to arise from it.*

"In proportion as the gold is exhausted do we get the three degrees of failures noted, in the order in which they are given. If the gold is only a little more than half gone, the toning becomes slower and slower, and the longer the prints are in the bath the poorer and less bright are the resulting tones and the image. Then come the yellowish-pink stains in the half-tones. Finally, when all the gold is gone, we get an apparent toning on the surface, and such prints turn yellow in the fixing bath. This last defect can only occur when the photographer neglects the instructions to judge his prints *by looking through them*, for when the bath is in this condition he would at once see that the prints when looked through retained all their original warmth of colour, and were not toning at all.

"When the toning bath is working properly the prints will on the surface appear over-toned, and be a bluish purple, and toning be complete in, at the most, ten minutes.

"The prime cause of these troubles may arise in one or two ways, either exhaustion of the gold by actual consumption and deposition on the prints as above indicated, or by precipitation from the presence of impurities in the bath, such as dirty bottles or dishes, impurities in the water or in the sulphocyanide. If the gold is simply used up, the bath may be replenished, as mentioned above, by the addition of more gold, in the same proportion as when the bath is first made up; but if it is due to precipitation, the bath is useless and should be at once thrown away and a new one made, taking care to avoid the same evil again.

"If these points are borne in mind, I state most emphatically that the toning of Ilford P.O.P. presents an absolute immunity from failure, and if any one does fail I shall be more than pleased to receive specimen prints and tone them in exact accordance with the formula, and return them to the senders.

"There are one or two general remarks which may be made with advantage. First, as to sulphocyanide: If care is taken to obtain it from photographic chemists or dealers there is little chance of its being impure. It is best kept in a solution of known strength and the gold added as wanted. Experience has taught us that it is not at all objectionable to make it up and use it at once; it is unnecessary to make it twenty-four hours before use."

(J. Hendrik, in a note to the *Chemical News* last year, pointed out that one sample of sulphocyanide examined by him contained only 31 per cent. of sulphocyanide, the remainder being chloride of potassium. Mr. Howson's suggestion as to keeping this salt in a solution of known strength is well worth adoption by everyone. A stock bottle of sulphocyanide of potassium or ammonium once opened absorbs moisture very rapidly, and the stock soon becomes a pasty semi-liquid mass.)

"The Ilford paper, as a rule, prints out purple, and another slight modification of the original instructions may be mentioned, viz., that the prints do lose somewhat in the toning, etc., and should be therefore a little over-printed.

"During damp weather, or if the paper is allowed to be damp at all before or during printing, the colour of the image becomes red, and if the damp is unequally distributed, it will give patchy prints. If these prints are printed a little deeper than usual, and toned in a bath rich in gold to a deep purple, this unevenness will entirely disappear.

"The richer and darker the tones required, the more gold must the bath contain. This is, of course, a point well understood in connection with albumen paper; and in this connection reference may be made to the toning bath recently mentioned by Mr. Welford, who recommends 4 gr. of gold to 6 oz. of water. This is five times as much gold as used in the Ilford formula, and would naturally produce darker toned prints. I may add that the same excess of gold acts just as well with the Ilford sulphocyanide (30 gr.) bath, and that this bath has the additional advantage in that it will keep, which is not the case with Mr. Welford's bicarbonate bath."

(Mr. Welford's formula is:—

Chloride of gold .. .. .	4 gr.
Bicarbonate of soda .. .. .	90 "
Water .. .. .	6 oz.

and he claims for this bath the following advantages:—"The bath is made at time of use, is very simple, tones quicker than any other, no uneven toning, overtoning impossible, and gives a

pleasing grey-black tone. We would remark that in our hands this bath is far too vigorous, and that making the total volume of the bath measure 9 oz. improves by slowing its action.)

"Beyond the defects and their causes which I have mentioned, there are, of course, those arising from sheer carelessness, such as contaminated dishes or fingers, or hypo or dirt stains on the prints before or during toning, but it is unnecessary to dwell on these, as such defects are usually readily traced to their true cause.

"Absolute defects in the paper itself are very rare, but do, of course, occur in a few instances, and they also are readily recognised. There are, for instance, small round spots which print out red and tone white, such as are caused by minute specks of iron in the actual paper. These spots do not, I think, exist in the present Ilford paper, though sometimes found in that we have discarded some months ago. Another defect in the paper is the presence of a narrow, straight band across the paper of deep purple, accompanied by a similar band of light red. This defect is rarer still, and one I have not seen for many weeks. If it should occur, the paper should be returned, and will be exchanged.

"I have only to say further that the remainder of our instructions should be strictly adhered to, if the greatest success is to be attained with the least trouble. We have probably more experience of the paper than any individual, and at the same time we have the greatest interest in making its use simple and popular, and our experience may therefore be relied on as pointing the best means of use.

"Impure hypo may cause stains or yellowness when the print is in the fixing bath, and such hypo should be at once discarded and new obtained. It is almost useless to attempt to doctor it."

In addition to the above notes by Mr. Howson, we would suggest the following as also conducive to absence of failures:—

In washing the prints prior to toning, it is absolutely essential to change the first washing water as quickly as possible, otherwise a distinct yellow tinge is imparted to the paper and gelatine.

When using the simple sulphocyanide bath recommended by the makers of the P.O.P., it is just as well to bear in mind that all samples of chloride of gold are not neutral, and it is advisable to make the solution of gold distinctly alkaline. Our method of using this bath is as follows:—To dissolve the gold in, say, 2 oz. of water, add 30 or 40 gr. of bicarbonate of soda, stir well, and add to the sulphocyanide dissolved in the 14 oz. of water. Many operators do not wash their prints before toning, but this is liable to cause sulphur toning, as most papers, and we believe the P.O.P. also, contain free acid, which, introduced into the toning bath, would cause decomposition of the sulphocyanide.

⚡ This paper may be used with any of the combined baths, but for information on this point, see pages 12 and 22 of our issues of July 1 and 8. We have so often warned our readers against the use of plain alum solution that it seems almost unnecessary to refer to it again, but the alkaline chrome alum solution recommended by Dr. F. Stolze should alone be used for chloride papers. This is prepared by dissolving five parts of chrome alum in 100 parts of water, and adding solution of ammonia drop by drop till on shaking a permanent cloudiness is formed. The solution is then ready for use after filtration.

## The "Barnet" Dry Plate Factory.

SITUATE about half-an-hour's run from the very centre of the City on what may be considered a continuation of the Highgate heights High Barnet is a place well worth visiting. Although so near London, one loses entirely all the smoke and grime, and the day we visited Messrs. Elliott and Son's factory was perfect in weather, a magnificent sky, plenty of sunshine, and a pleasant breeze to temper the great heat.

We were met at the station by Mr. Birt Acres, the Manager, and after a few minutes' walk reached the factory, which from the outside presents a very pretty appearance, the frontage of the two houses being gay with flowers of all sorts. Certainly one would never suppose that behind this charming exterior so much business was carried on.

Our first visit was to the glass cleaning department, where we found several hands busily engaged in washing the glass subsequently to be coated with emulsion. After cleaning and drying, the glass is carefully examined for faulty cutting and defects, and from an examination of several stacks of glass, we were astonished to see how even and regular it was in thickness, and how scrupulously clean.

In the emulsion making room we were introduced to Mr. Hubert Elliott, the head of this department, who kindly explained the process of mixing and cooking the emulsion, this latter process being conducted in special ware jars, which are placed in a series of water baths, which are heated by means of gas. Here we need hardly state that the room was rather darkness visible than light, but after entering the room where the emulsion is washed, which was absolutely without light of any kind, we came to the conclusion the emulsion making room was well lit.

No special arrangements had been made for our visit, but as the demand for the Barnet plates has increased so much, we were able to see every part of the business in full swing, so that on our entering the coating room we were able to see the coating machine, one of Cadett's, in operation. With this machine the emulsion is brought up to a given temperature by the aid of a steam jacket, and is then fed into a silver trough, also steam jacketed; from this trough the fluid emulsion is pumped by a series of silver pumps, which are geared so as to work at any given speed, and any number of these pumps may be used so as to correspond with the size of the plate to be coated. The emulsion flows over a silver roller, and from this just the requisite quantity of emulsion is evenly distributed over the surface of the glass.

The glass as it is fed on to the travelling bed of the machine lies edge to edge, but after coating it passes over a series of rollers by means of which the plates are slightly separated; then the backs are mechanically cleaned, and the plates pass on over the endless bands, which work in ice-cold water, which just touches the underneath surface of the glass, thus thoroughly setting the emulsion by the time the plates reach the end of the machine, where they are cantled up, so that the machine minder may lift them on to the racks, which when full are transported by a lift to the drying room, which is kept at an even temperature by means of filtered air, drawn through the rooms by a series of exhaust fans.

As soon as dry the plates are taken to the packing room; here each plate is very carefully examined for defects, and no matter how small the defect, the merciless examiner condemns it, for, as we were informed, "It is only by such extreme care and ruthless throwing out of defaulters, our firm has made its reputation for the uniformity and excellence of our plates."

From the packing room we pass to the stock rooms, where we were informed that a very small stock at present remained, so great has been the demand for Barnet plates this season.

Thence to the testing department, and here let us at once say we were much struck with the method adopted. We found no useless sensitometer, but two plates, one of known quality and one to be tested, are placed in a camera side by side, fitted with accurately paired lenses; they are then exposed simultaneously to the same light and on the same subject, and then together developed and fixed. Nor is the developing done with pyro and ammonia only, but pyro soda is also used.

The building throughout can be heated with steam pipes and kept at an even temperature without the use of a naked light or fire. Wherever necessary, double doors are provided, to which a very ingenious arrangement, devised by Mr. Birt Acres, is fitted, by means of which it is impossible to open one door without the other being shut. We have now, with the exception of the stock rooms where raw material is kept, described the whole of the building devoted to plate making, but perhaps an equally, if not more interesting portion of the factory has yet to be visited; this is the printing and enlarging department.

Messrs. Elliott and Son are perhaps the largest trade printers in England. Silver, bromide, platinotype, and carbon, both small and large, are undertaken, and possibly many of our readers are possessors of work done by this firm, though they may not know it, as Messrs. Elliott and Son print largely for amateurs through dealers.

The silver department was first visited. Here we find huge stocks of albumenised paper, next door the sensitising department, and outside, in the open air, table after table covered with printing frames, whilst, in wet weather, galleries at the top of the buildings are used for this purpose. To the toning-room we next turn, and here we see the head of this department busy with about six dozen prints at once in his toning-bath. On our asking whether blisters were ever met with, this gentleman said, "Well, sir, I had a few in the winter, but I never get them in the summer," and on our asking for his remedy, which would be of interest to our readers, he said, "Tell them to keep all their solutions at one temperature, and they won't get blisters."

In the platinotype department we see evidences of plenty of work going on here; but the most interesting of all the printing departments is that devoted to carbon printing, of which Messrs. Elliott make a great speciality, and show some very fine results.

First in "the kitchen" we see the grinding of the pigments, then the preparation of the pigmented gelatine and the coating of the paper, and finally we go to the developing room. Here we find

several men at work, and one busy on a print measuring 34 by 44 in., a size which would probably frighten some of our readers if they were called upon to handle, but which does not seem to be out of the usual here. Opals, opalines, oval, round, and square plaques are also to be seen, and, in fact, carbon prints in every size, stage, and finish.

The bromide enlarging department is next visited. Here we see a bromide print exposed and developed, and then next door the making of enlarged and reversed negatives. We waited while one negative was enlarged and developed, and on our remarking, "That's a decent sized plate—what is it?" we were gravely informed, "Oh no, sir! this is only a small plate, only 24 by 18 in." We were later shown some large, or what they call large plates, measuring 36 by 48 in. One of the most striking features is the sensitising bath for large plates, which is of special construction and very ingenious.

Other departments we visited were for the mounting, spotting, and finishing of prints, where, as in the others, system and careful business management are evident.

The factory of Messrs. Elliott and Son is well worth a visit, and we have endeavoured to give some little idea of what we saw there in the above description. We finally took our leave bringing away with us some of the Barnet plates for our own trial, of the results of which we shall hope to say a word or two in a week or so.

## Holiday Resorts and Photographic Haunts.

### GLOUCESTER AND NEIGHBOURHOOD.

By W. H. H.

THE lover of architectural photography will find much to interest and please in this old city and the surrounding neighbourhood. Gloucester also has the advantage of being a great railway centre, easy of access, and affording a large number of excursions within easy reach. The cathedral is the first attraction. The exterior is difficult to make a picture of, owing to the rather confined situation; the choir also is of considerably greater height than the nave, giving the building a somewhat hump-backed appearance. The tower is a magnificent structure, one of the finest in the country, and the beautiful south porch should also be noted. A good view, almost the only one, is obtained from the north-west corner of the Close (just by the old gate) in early spring. Later, this view is greatly obstructed by trees, though even then a good view of the tower can be obtained. Notice also the picturesque deanery, the prior's house of the old abbey, and the memorial to Hooper the martyr. The interior is most interesting; few cathedrals being richer in detail. First we have the grand Norman nave; the fine perpendicular choir; the highly interesting Norman ambulatory, one of the very few surviving; the lady chapel, St. Paul's Chapel, the reliquary, the tombs of King Edward II., Osric of Northumbria (founder of the abbey), Duke Robert of Normandy, and the beautiful Morley monument, by Flaxman; last, but by no means least, the exquisite cloisters, with their splendid fan-vaulted roofs. Permission to photograph is readily granted by the Dean (Dr. Spence), which, to prevent disappointment, should be obtained beforehand. (I may as well here state that all cathedrals require permits from the Deans before any photography can be allowed in them. The vergers have no authority to grant permission. The only exception is York Minster, where permits are issued by the Chapter Clerk). The town itself has not much of interest, being old without being over-picturesque. The adventurous photographer who mounts to the top of St. John's church tower will be rewarded with a fine general view of the cathedral; there are also one or two distant views to be had from the Severn banks, though generally marred by ugly railway viaducts in the foreground. The surrounding country is very full of interest; there are Tewkesbury Abbey and town, worth a long day, Malvern, Worcester, Cheltenham and Leckhampton, Cirencester, Stroud and Brimscombe, Hereford, Ross, Tintern and Chepstow, Bristol and Clifton, and Berkeley. All these are easily reached by rail, and are within the limits of a day's excursion. The tourist will find plenty of good hotels at Gloucester, to suit all purses. Enough has been said to show that a holiday could pleasantly and profitably be spent in this old town on the Severn. Though on photography intent, the attractions of Severn salmon and Gloucester cheeses need not be overlooked.

## The Society's Standards.

THE Standards adopted by the Society in 1881 have been carefully reconsidered to see what additions or modifications were desirable.

The following statement is complete so far as the subjects it deals with are concerned:—

### LENS DIAPHRAGMS.

It is recommended:—

- 1st.—That the aperture of the standard-unit diaphragm have a diameter equal to one-fourth the equivalent focal length of the lens.
- 2nd.—That diaphragms with smaller openings have apertures diminishing in area to the extent of one-half from the unit standard downwards.
- 3rd.—That every diaphragm be marked with its intensity ratio, and also with the relation that the diameter of its aperture bears to the equivalent focal length of the lens, thus:—

$$1 \frac{f}{4}; 2 \frac{f}{5.6}; 4 \frac{f}{8}; 8 \frac{f}{11.3}; 16 \frac{f}{16}; 32 \frac{f}{22.6}; 64 \frac{f}{32};$$

$$128 \frac{f}{45.2}; 256 \frac{f}{64}; \text{etc.}$$

Should a lens not admit of a diaphragm with an aperture as large in diameter as one-fourth its focal length, nor exactly any one of the above-mentioned sizes, it is still recommended that all the apertures be made in uniformity with the above scale, with the exception of the largest, which should be marked with the number its area requires in relation to the unit diaphragm. In the case of a lens having a working aperture exceeding in diameter one-fourth its focal length, the diaphragms should be marked according to the sizes of their relative apertures, for example:—

$$0.5 \frac{f}{2.8}; 0.25 \frac{f}{2}, \text{etc.}$$

And diaphragms which require to be made with apertures intermediate to the standard sizes should be marked in a corresponding manner.

### LENS MOUNTS AND FITTINGS.

It is recommended:—

- 1st.—That the equivalent focal length of each lens be engraved upon its mount.
- 2nd.—That the following series of screws for photographic lens flange-fittings be adopted:—

Diameter in inches.	No. of threads per inch.	Core diameter in inches.
1	24	.9466
1.25	24	1.1966
1.5	24	1.4466
1.75	24	1.6966
2	24	1.9466
2.25	24	2.1966
2.5	24	2.4466
3	24	2.9466
3.5	12	3.3933
4	12	3.8933
5	12	4.8933
And upwards, advancing by inches.	12	

The form of thread is that known as Whitworth's Angular Thread, and is designed as follows:—

Two parallel lines, at a distance apart equal to 0.96 of the screw pitch, are intersected by lines inclined to each other at fifty-five degrees. One-sixth of the vertical height of the triangular spaces so obtained is rounded off both at the top and bottom, leaving the form of the screw thread. The depth of this thread is 0.64 of the screw pitch.

- 3rd.—That every flange and adapter have a mark upon its front to indicate the position of the diaphragm slot or index of any lens when screwed home. The mark on any adapter should coincide with the mark upon any flange into which it is screwed. This mark should be placed at the point at which the thread becomes complete at the shoulder of the flange or adapter.

### CAMERA SCREWS.

It is recommended:—That all screws fitted to cameras either for attachment to the stand, for fixing rising fronts, or for other movable

parts, be either  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ , or  $\frac{3}{4}$  of an inch in external diameter, and in pitch of thread and other details in accordance with the generally recognised Whitworth standards for these sizes.

The above is an extract from the *Journal of the Photographic Society of Great Britain*, and forms a fitting prologue to a recent improvement introduced by Messrs. Taylor, Taylor, and Hobson, of Leicester.

It is no uncommon thing to see a worker try for two or three minutes to screw a lens into a flange, and it requires considerable knack to be able to start the usual form of screw at once, from the difficulty of knowing at what point in the revolution the threads first engage, and the difficulty of holding the screws in correct relation axially.

Messrs. Taylor, Taylor, and Hobson's invention entirely meets this difficulty. In order to describe it fully it is necessary to refer to the system designed by them for providing that all lenses fitting the same flange are held with their diaphragm indexes or other fittings in one uniform convenient position. The present invention is a supplement of that system.

By arranging that the threads of male flange screws upon lens mounts should terminate at their shoulders in one uniform position in relation to the diaphragm indexes, it was provided that they might all screw home with their diaphragm indexes in one convenient position. In the present invention, by arranging that the threads commence abruptly in a similar uniform position in both male and female screws, it is provided that any lens when presented to its flange with its diaphragm index uppermost, or as it is arranged to be used, is in position, on being turned, to at once engage with the screw of the flange.

The illustrations show a Standard flange and an adapter in the position of rotation at which the screws would immediately engage on being turned. This position is shown by the zero marks, which would again coincide when the flange and adapter have been screwed together. In the same way any properly constructed lens would screw into the flange or adapter; its diaphragm index being at zero at the commencement and completion of the engagement.

So far it has been shown how this invention decides at what part of their revolution the screws shall first engage. The enlarged portion of a Standard adapter seen in the illustration exhibits the manner of forming the male screw thread to commence abruptly near the zero, and it will be understood that both the internal and external screws are formed similarly in this respect.

The common practice of merely chamfering or bevelling the ends of screws, which leaves the threads to terminate, not abruptly, but to die away gradually in the course of revolution, not only makes it difficult to find the position for first engagement of the screws, but by forming the chamfers into a kind of ball and socket, makes it hard to determine their correct position axially.

It will be seen that this method of removing this usually incomplete portion of a thread, and forming a cylinder at its root, provides a clear shoulder and bearing which determines the true axial relation of screws when placed together for engagement.

For convenience and uniformity the zero of a screw and its abrupt commencement are at that part of the revolution at which the point of a tool cutting the female screw would lie in the plane of its face or shoulder.

It must be borne in mind, however, that this applies only to a screw of absolutely correct size and form, for any error in the dimensions of a screw would cause corresponding displacement of its true zero.

For some time past, in view of the importance of accuracy in these matters, Messrs. Taylor, Taylor, and Hobson have given atten-

tion toward the improvement of appliances for making and measuring screws, with the result that they now prepare all screwed fittings within a limit of error of one-thousandth part of an inch on their diameter, and confine the error on that side of the normal which secures perfect and free interchangeability.

The standard 2 inch lens flange and 2 to 1.5 inch standard adapter forwarded as a specimen of this improvement immediately strike one by their perfection of finish and the ease with which the adapter is screwed into the flange. Whilst standards of sensitiveness, of light, etc., are essentially important, none less so are the standards of screw and camera fittings, and we hope that this the latest improvement will find universal adoption by the photographic world, so that one may on purchasing a new lens, of whatever make, know that at once it will fit a given flange or adapter.

## Harmonising Harsh Negatives.

(Continued from page 146.)

It follows that only in a few exceptional cases the compression of the whole scale within the limits of our process will yield satisfactory results. A practical difficulty will also be found in gauging in the dark-room, during the process of development, the exact amount of compression necessary. The introduction of two scales into the composition, or the compression of one end of the scale, will be found more generally useful and pleasing. Reduction or intensification will effect the latter result.

The intensification of a flat negative showing too compressed a scale will show a result somewhat as if a darkish print had been made from the negative in its original state, and the lights put in with white crayon; or when the negative happens to be dense as well as flat, relief may be obtained by clearing out the shadows with a reducing agent. If this be crisply done, the result will be as if a light print had been taken from the negative in its original state, and the shadows strengthened with black crayon. If these methods be applied locally, two scales are shown in the print; if applied generally, the effect is that of compressing one end of the scale, and rendering the other more fully. For some classes of subjects these methods will yield pleasing results.

In the case of harsh negatives, where the shadow detail is already too thin and the lights too dense, neither of these methods is quite satisfactory. In attempting to reduce the high-lights which penetrate through the film to the support, it will only be by the exercise of an amount of manual dexterity not usually possessed by an amateur, and then at the expense of a vast amount of time and patience, that we can avoid clearing away the shadow detail lying on the surface of the film when the light and shadow are intimately mingled.

When the lights and shadows are in masses and soften into each other, the lights may be satisfactorily reduced by means of Mr. Howard Farmer's reducer (hypo and ferrieyanide of potassium) applied by a sponge. A member of our Society, Mr. Beadle, is very skilful in the use of this agent, and has kindly lent me some prints from negatives before and after reduction, which I pass round for inspection. In the prints of the chapel interior you will note the great improvement in the columns, font, and the wall upon which the light falls so strongly. In the landscape you will note how charmingly the distance prints out from the reduced negative.

The difficulty in using this method is to avoid reducing the shadow detail adjacent to the lights, and to avoid a patchy appearance due to unequal reduction. The same remark will apply still more strongly to the use of spirit applied with wash-leather, as some pressure has to be applied, and if the portions to be reduced are at all large the difficulties become very great. I have never seen an instance of a large portion of a negative reduced with spirit without patchiness appearing, generally accompanied by a smeary effect.

It is not necessary for me to give here formulæ for the many intensifiers and reducers extant, each of which has its own advantages for special purposes. A full list of these with useful comments and explanations will be found in the admirable paper read before our Society last year by Mr. Roland Whiting. I may, however, call your attention to one which has been referred to lately at some of the Societies. The formula as given by Mr. Teape at the London and Provincial is:—

Bichromate of potassium, saturated solution	..	1	dr.
Sulphuric acid	.. .. .	1	"
Water	.. .. .	8	oz.

This is a stock solution to be diluted for use according to the purpose for which it is required. For instance, if it is only necessary to clear away a slight surface fog before intensification it should be diluted to a pale lemon tint. When dense negatives have to be reduced, a stronger solution may be used. I have found it speedy, and when applied to the whole surface of the negative in a bath regular in its action. The effect is visible during the operation, and as hypo is not used a lesser amount of washing is necessary that when that useful but troublesome chemical is employed. (To be continued.)

## Apparatus.

### AMIDOL.

In our issue of June 10th we gave a translation of a note by Dr. Eder on the above new developing agent, which has now been introduced into England by FUERST BROS., of 17, Philpot Lane, E.C. We have had this under trial now for nearly three weeks, both for time and instantaneous exposures.

The solution recommended by Dr. Eder is:—

Amidol .. .. .	5 parts.
Sodium sulphite .. .. .	50 "
Distilled water .. .. .	1,000 "

Snap-shots developed in this solution gave us very good negatives. The image appears almost instantaneously, even with extremely short exposures, and gives them the appearance of over-exposure, but on allowing development to continue we found we had some very good negatives with full printing density. The colour of the negatives is a fine greyish black, much resembling the image given by Eikonogen.

Tested against pyro and ammonia, we found that it would give softer negatives, quite as full of detail, but without the slightest sign of fog, an advantage which will be of great service in snap-shot work. In time exposures, where over-exposure was known to exist, we found the addition of about one grain of bromide of potassium to every ounce of developer was an advantage. As accelerator a solution of sodium sulphite was used as recommended by Eder, with very good results.

Amidol is a developer which we think likely to be of considerable service, and we shall continue our experiments, trying it for bromide paper and lantern slides.

The following reports by Messrs. Spiller and Addenbrooke are also of interest.

Mr. J. Spiller says, "I have now made a considerable number of experiments with the two new developers, and reserving the *Metol* for future report, I may say at once that the *Amidol*, as tried upon six different qualities of commercial plates, has given me eminently satisfactory results. It is easy of application, and possesses special properties which will recommend it to the notice both of professional and amateur photographers.

"The fact that it can be used in a sulphite solution alone, *without any admixture of free alkali*, is an important consideration in its favour, and thus dissolved, it is sufficiently permanent to serve as a one-solution developer, being diluted for use with three or four times its bulk of water immediately before employment. The stock solution, in concentrated form, was made up according to your instructions as follows:—

Distilled water .. .. .	1,000 parts.
Sodium sulphite .. .. .	200 "
Amidol .. .. .	20 "

"Further diluted, as already stated, and used with a small proportion of potassium bromide as a restrainer, the images can be made to appear with any required speed and the density modified merely by altering the strength of the developer; the resulting negatives seem uniformly clear and brilliant without any trace of fog. Tourists especially would find it most convenient for general use, but they should be advised to carry always with them a small supply of potassium bromide in crystals, so as to be ready for all emergencies.

"I cannot speak too highly in praise of *Amidol* as a developer, for with it the operator has his process completely under control. I find, moreover, that it is quite easy to develop many plates in succession with the same solution, which is not the case with pyrogallol."

Mr. Addenbrooke sums up as follows: "Full printing density is attained in from three to four minutes. With thinly-coated plates it is advisable to wait until the action of the developer is strongly apparent at the back of the plate; but if the film is a thick one, the image need only just appear through. After fixation, the deposit is of a good black colour, inclining to a greenish tinge as the proportion of bromide is increased. The shadows remain quite clear, and the film perfectly free from stains."

## Societies' Meetings.

**Birmingham.**—At the weekly social meeting held on the 23rd ult., the members assembled to welcome Miss C. W. Barnes, of New York. During the evening about fifty slides, comprising views of Birmingham, Warwick, Kenilworth, Stratford-on-Avon, Wootton-Woman, Broom, etc., were put through the lantern by Mr. E. H. Jaques. Mr. E. C. Middleton described the different views as they appeared on the screen.—Ordinary meeting held on the 25th ult., Mr. G. F. Lyndon in the chair. Three new members were elected. Reports were read of excursions to Berkswell, Wixford, Warwick, Aston, Cantlow, and Kenilworth. Miss Barnes accompanied the members on the latter excursion. Messrs. Marion and Co. sent a sample box of dry plates for the purpose of illustrating their new system of packing, the object of which is to secure a packing perfectly non-injurious to the film. The system met with the unanimous approval of the members present. The thanks of the meeting were accorded to the Paget Prize Plate Co. for their kindness in sending a large parcel of sample boxes of their well-known dry plates for distribution amongst the members; also to the Editor of the *AMATEUR PHOTOGRAPHER* for a copy of "Amateur Photographer's Annual" for 1892, to the Editor of *Photography* for *Photography* reading cases, and to Messrs. Fry and Co. for a copy of A. R. Dresser's work on "Bromide Enlarging." The Chairman announced that the judge had awarded the prize offered in connection with the Development Competition held in July, to Mr. George Wilkes. The enlargements offered by the society for the best prints from negatives taken on the Berkswell and Wixford excursions were awarded to Mr. E. Underwood and Mr. Sears respectively. It was moved by Mr. E. H. Jaques and seconded by Mr. E. C. Middleton, "That the hearty congratulations of the society be offered to the President (Sir J. B. Stone) on the occasion of his receiving the honour of knighthood from the hands of Her Majesty the Queen. A discussion on "Hand-Cameras and their Work" was opened by Mr. Jaques. Messrs. Griffiths, Middleton, Sheaff, T. Taylor, Thomason, Underwood, and the Chairman took part in the discussion, which was of an extremely interesting and instructive character. Several hand-cameras were exhibited and described. Miss C. W. Barnes then delivered her paper on "American Work and Workers."

**Hackney.**—On the 23rd ult., Mr. Hensler presiding, Mr. Geo. Hankins nominated for membership. Members' work shown from Messrs. A. Barker, Dean, Hensler, and Sodeau. Borax recommended to be added to the toning bath for P.O.P. Mr. R. Beckett read a useful paper on the "Suitable Printing Process for a given Negative," recommending the following bromide rapid paper at great distance from light for thin negatives:—*Bromide slow paper*: Longer exposure and thicker negative. Bromides generally require a thin negative with a compressed scale of gradation. For enlarging, avoid hard or yellow negatives. The greater the distance the more latitude. Always make a test exposure. Contact printing exposure must always be exact. Ferrous oxalate developer best, half old, half fresh. *Alpha paper*: Half tones must not be too heavy. Over or well expose. Should develop red colour, can then tone all shades from red, brown, black, to blue. Developer recommended, hydroquinone with eikonogen mixed; can be used over and over again. To mount Alpha paper with polished surface, paste waterproof paper on back (black side outwards) after squeegeeing. Use glue and treacle or glue and glycerine, work up to a froth on a board, hold print in hand, dab on and off several times in the same way that boxmakers do, till sufficiently glued, and place on card mount. *Gelatino-chloride paper*: Same treatment. *Platinotype*: High lights must not be heavy; use the new cold-bath process. With this paper the delicate tones do not fix out much. *Carbon tissue*: Best for all above whole-plate. Thick pigment for thin negatives, and *vice versa*.

**Leightonstone.**—Special general meeting held on 24th ult., Dr. W. Pickett Turner in the chair. A proposal was brought forward from the Photographic Society of Great Britain setting forth the advantages of affiliation with them. After a discussion it was decided to become affiliated, the Secretaries being requested to take the necessary steps. Mr. A. E. Bailey next opened a discussion on the experience he had had with the Barnet plates recently distributed among the members. He had found them rather quicker than the usual run of ordinary plates, and developed up very clean and rich in silver, giving a very brilliant negative. Having passed round, some half-plate negatives taken at the club's outing at Barnet Mr. Cuffey asked the formula they had been developed with. Mr. Bailey replied, with pyro and ammonia, 10 per cent., 60 minims each; pyro, potass. bromide, and ammonia to 2 oz. Mr. Cox said he had difficulty with air bubbles. Mr. Bailey, in reply, said he had no difficulty in that direction if careful to well dust the plate and flood with water before pouring on the developer. The discussion was continued by the President, Messrs. Wates, Wire, Reddick, Cox, Prockter, etc. The Hon. Secretary next introduced a new printing frame, the Bynoe, sent down by Messrs. R.

and J. Beck, which was admired on account of its simplicity and freedom from casting shadows, but most of the members were rather dubious as to the print not shifting. The Hon. Secretary undertook to test it, and report his experience. A large parcel of Paget plates received from the Paget Prize Plate Company were next distributed among the members, as were also specimen packets of the new gelatino-chloride paper of the Eastman Photographic Materials Company. The Hon. Secretary asked members to keep note of their experience of them, by them, as a discussion would be held later on as to their merits. Several other matters were gone into, and the exhibition decided to be held on November 10th, 11th, and 12th, at the Masonic Hall, Leytonstone.

**Liverpool.**—The ordinary monthly meeting was held on the 25th ult. The President, Mr. W. Tomkinson, occupied the chair, and there was a good attendance. Messrs. E. T. Cockerham, A. S. Clare, A. A. Vos, and H. Anderson were elected members of the Association. Mr. Marriott showed some specimens of home-made ground glass, which he explained were produced by simply taking two spoiled negatives, placing a little fine sand and water between, and grinding them together for a short time. The surface was all that could be desired either for focussing screens or any other photographic purpose. Mr. F. H. Elsby gave a demonstration on the use of the Society's enlarging and reducing camera, showing the various movements, and explaining how the exact position for any required size could easily be ascertained by means of marked rods which were provided for the purpose. For the benefit of the younger members, the President then demonstrated the development of under-exposed and over-exposed plates. Under the same conditions as to light, stop, and subject he had exposed two Castle plates, one for about one-twentieth of a second and the other about five seconds, and from each he now developed a very good negative. Several gentlemen gave their experience of the Paget Prize Plates and of the Eastman printing-out paper, samples of which had been distributed amongst the members. The opinions expressed were mostly favourable. The Secretary exhibited Beck's new printing frame, which enables the whole of the print to be examined at once without fear of movement. An excursion to Shrewsbury was announced to take place on Saturday.

**North Middlesex.**—A meeting was held on the 22nd ult. In the absence of Mr. Wall Mr. Walker took the chair. Forty-five members and friends were present. The Chairman introduced Mr. Debenham, who addressed the society upon the subject of "Transparencies by the Carbon Process." He recommended that the tissue should be bought unsensitised, and sensitised as required by this formula:—Bichromate of potassium, 1 oz.; ammonia, 1 dr.; water, 30 oz.; or, if the tissue had to be kept for some time, it would be well to increase the water to 40 oz. About three minutes' soaking would be sufficient. It should then be squeezed on to a plate of glass (into the pores of which talc had been thoroughly rubbed), dried, and stored for use. It would strip with a bright surface, which would be in close contact with the negative. He recommended as an actinometer that a negative of medium density should be taken, and while the carbon print was being made that a print on silver paper should be made through a small opening in a mask. He emphasised the necessity of a safe edge to the carbon print, and that the cut-out mask for that purpose should be placed outside the negative instead of between the negative and the tissue. By this means the safe edge would be vignettied off instead of showing a hard line, and there would be less risk of frilling in developing the print. It was necessary that the print when placed in the cold water prior to development should be squeezed on to a sheet of glass before it had absorbed all the water it was capable of holding, otherwise it would be unable to take up the film of water on the glass, and close and permanent contact would not be made. Mr. Debenham illustrated his lecture by diagrams on the blackboard, and by passing round transparencies, etc., in various stages of progress. He then proceeded to develop several prints, calling attention to the precautions necessary to secure good results. Many questions were asked and answered, and a vote of thanks was moved by Mr. Marchant, who said the Society was indebted to Mr. Debenham and to the Affiliation Committee of the P. S. G. B., who had made the arrangements for the interesting and practical demonstration just delivered. Mr. Cox seconded the motion, which was carried with acclamation. The usual competition of views taken at field-days was held, the vote of merit being secured by Mr. A. G. Hewson for West Hampstead. A large number of plates kindly sent by the Paget Company were distributed, each member present receiving a packet. Attention was called to the Hill-Norris dry collodion plate, particulars of which had been received. The next meeting will be held on September 12th, when Mr. H. Smith will take the chair, and Mr. Beadle will demonstrate the making of lantern slides on various plates. Visitors welcome.

**Phot. Soc. of G. Britain.**—Technical meeting, August 23rd, Mr. J. Traill Taylor in the chair. Samples of Amidol, the new developer

and of Richards' patent corners were laid upon the table. "Portraiture other than in the Studio" being the subject for discussion, Mr. J. Nesbit passed round photographs of the Chairman, Messrs. Cowan, Dunmore, and others, which he had taken out of doors, in an angle of the walls of his house. He used a Ross' Rapid Symmetrical, and found that it gave such sharp definition as to render retouching necessary, and called attention to two prints from the same negative, one untouched, the other after Mr. Redmond Barrett had retouched it, the latter being a very satisfactory likeness of Mr. E. Dunmore. He had opened out such a lens as mentioned to an aperture of about  $f/6$ . Mr. J. Weir Brown exhibited some portraits taken in an ordinary room near a double window, using a white reflector; he found it possible to avoid the duplication of the light spot in the eye by controlling the angle of the reflector. Mr. Chapman Jones had not been troubled with the secondary light spot. Mr. Debenham said the larger the reflector the less bright it might be, and the less chance there was of a second light spot. For indoor portraiture he preferred to put the sitter a little out of the full light from a window, on the other side of which, and close to the wall, is placed the camera. The reflector he would put from the camera almost up to the sitter; an arrangement which masses the light on the prominent part of the face. He illustrated his arrangement on the blackboard, and exhibited a number of portraits taken in that manner. In reply to Mr. Samuels he said he generally placed the reflector perpendicularly, but if of a plain white character this was immaterial. The Chairman described Solomon's system of portraiture with magnesium, which he found gave flat results. A method he had adopted was to place the sitter in front of a window with the camera on the outside. An improvement on this was to place a mirror in the window, and photograph the reflected image with a camera by the side of the sitter; the effects of lighting in this manner were very beautiful, and if the angle of reflection were not acute there was no secondary image with an ordinary looking glass. Mr. Dallmeyer remarked that the law with regard to reflections from polished surfaces held good with dead surfaces, the difference being one of degree only. The Chairman suggested the term "radiator" rather than reflector for a dead surface. After further discussion the Chairman announced that the next meeting will be held on September 27th, at 5a, Pall Mall East, and the meeting adjourned.

**Richmond.**—At an informal meeting held on the 26th ult., the President in the chair, Mr. G. W. Ramsay brought some fine studies of sea and cloud taken from his yacht, and some printed on rough drawing paper. Mr. Cembrano, jun., showed a copy of the Convention group taken on a whole-plate by Mr. J. Stuart, of Glasgow, which showed remarkable definition and good detail, although taken with a drop shutter and lens at  $f/12.5$ . The lens used was one of Zeiss's of  $7\frac{1}{2}$  in. focus. Mr. Ennis had a series of experiments on toning Ilford P.O.P. paper, showing a great variety of colour from red brown to black, the first colour being obtained by one minute's toning in a combined bath, and the black by a quarter of an hour's immersion in the same bath. He further exhibited a print on the same paper, which had been exposed to sunlight during the last six weeks and one half of which had been covered with black paper; no deterioration or signs of fading were apparent. One of the members having asked which was the best way of stopping out pin-holes in a negative, Mr. Cembrano said that he used smoke black and a very finely pointed sable brush, No. 0; instead of water he preferred wetting the brush in his mouth; only the smallest amount of pigment was necessary, and in order to match the colour of the negative he would first try printing on the clear rebate of it. Mr. C. H. Davis showed Ross's divided camera with swing-back attachment. Messrs. R. and J. Beck sent for inspection the Bynoe printing frame, which has the advantage of being small, casting no shadow on the print, and enabling the operator to have a full view of same. Mr. J. B. Huddy was elected a member.

**Sheffield.**—At the usual monthly meeting of the Optical Lantern Society, held on the 18th ult., Mr. Clowes (Vice-President) in the chair, Mr. Mottershaw gave a paper on "Stereoscopic Transparencies." In the first place Mr. Mottershaw explained that his negative was an ordinary half-plate, cut in two after development, the two halves transposed, and then mounted with a piece of clear glass in the same way as a lantern slide. He then demonstrated the subject by printing from a negative so prepared, two transparencies, using Cowan's chloride bromide plates, and giving exposures (by gas-light) of 3 and 5 sec. respectively. The first was developed with hydroquinone (Ilford formula), the other with rodinal 1 part to 30 of water, with the addition of a little restrainer composed of 1 part brom. pot., 3 parts rodinal, and 3 parts water. The two plates treated in this way gave very satisfactory results, but so similar that it was hard to distinguish the one from the other. To finish they would require fixing, and then mounting with a piece of fine ground-glass at back.

**South London.**—On 15th ult. at Hanover Hall, Hanover Park, Rye Lane, Peckham, the President, Mr. F. W. Edwards, in the chair,

after the announcement of additions to the club library, a Newman and Guardia aluminium blind shutter, now being placed on the market, was shown by the Hon. Secretary, and was minutely examined by all the members present, and its working much admired, exposure ranging from 1-50th to 1 sec. being obtained by setting an index point. Time exposures can also be obtained. A celluloid focusing screen of the thickness of ordinary glass which Messrs. Newman and Guardia are fitting to cameras was also exhibited. Mr. H. G. Banks, one of the Vice-Presidents, then read a paper on "The Optical Lantern: its Construction and Use," during the course of which he gave a practical demonstration of the working of the lantern. In order to show the great heat generated when using the oxy-hydrogen limelight a penny was placed in the flame, and in less than a minute a hole was made through the coin.

**Tunbridge Wells.**—On the 27th inst. the members went by special invitation to Broomhill, the seat of Sir David Salomons, Bart., the patron of the Association. It was intended that the visit should be made on the 20th, but in consequence of the enormous amount of rain that fell the two days previous, Sir David, with his usual kind thoughtfulness for his guests, decided it was better to postpone it, and it was arranged for the 27th. The weather was threatening, but it was decided to go, and Broomhill was reached at 3 o'clock in a smart shower which turned out to be the beginning of a thorough wet afternoon, so much so that all thoughts of outdoor work were abandoned, and interiors were the order of the day. But Broomhill is one of the wonders of the district, so many extraordinary machines to be seen all worked by the electric current that the host gave a great amount of pleasure when he proposed going through the workshops, those who had been before whetting the appetite of those to whom this was a first visit. They were first conducted to the studio, the immense camera coming in for a large amount of admiration, as also several others. There is an arrangement for portrait-taking by the electric light, which is filtered through screens. A new table was being fitted up for microscopical work with a new kind of fine adjustment. One of the alterations here will be a new studio about 60 ft. long; fret saws, lathes, circular saws, milling machines, engraving and mortising machines (with the latter several stopper extractors were made and given to members), and a hammer working by electricity on the same principle as Nasmyth's steam hammer, a band saw with which a chair was made, watchmaker's lathe and tools for the very finest work possible. All these machines are fitted with lamps over, designed and patented by Sir David; they can be used in any possible way, having pulleys and weights so arranged that they will remain in position just as required; this is an important matter where particular work is being done for the light to be concentrated on any given spot. The dark-room came in for a fair share of attention; all the appliances, including the novel rocking table, the arrangement of the light underneath, and the mode of making it stand level on an uneven floor, showed wonderful skill in being well thought out. The new lens just made for Sir David is of quartz, and is supposed by experiments to be the fastest yet made; it was specially used for photographing the electric spark. A half-plate Dallmeyer extra rapid lens working at  $f/5$  was shown, and an electric photo-microscopical projecting lantern made by Messrs. Newton and Co. for Sir David Salomons, also a lecturer's lantern which would throw an arrow on the screen at the very spot where the lecturer wished to draw the attention of the audience; and several lanternists were much interested by the oxy-hydrogen lantern also made by the above-named firm specially to order. He also showed an arrangement he had for registering the lenses of his triple lantern on the screen. One set of these had the frames made of wood, and the other set in gun-metal frames which were the most exact, being so made that expansion of the glass by the heat was allowed for; another was for registering slides belonging to a set, and an ingenious rule for measuring from the centre with moveable square at end. There was also a kettle for boiling water and a glue pot both heated by electricity. The engine house was next visited, where there are two gas engines of fourteen nominal and thirty indicated horse power, used for working the dynamos which charge the accumulators. A novelty here was that the engines were made to start by an electro-motor, a windlass tightening up the band which gave the start. These engines have replaced those working by steam. From the engine room is a door leading to the accumulator room where all the storage is kept for the machinery in the workshop. Tea was served in the dining room, after which the picture gallery, saloon, and sculpture room were thrown open. The time having now arrived for the return journey all too quickly, waterproofs were donned to protect the owners from the downpour of rain, all returning feeling that their patron had once more shown the great interest that he takes in the members of the Association. It should be stated that Sir David Salomons had again given the members the privilege of inviting Mr. H. P. Robinson to join the party, which gave them a great deal of pleasure to have him with them.

**Uttoxeter.**—On 15th ult., the members of the above Society, to the number of about twenty-four, had a most enjoyable trip to

Chester. The party left Uttoxeter by the 7.30 a.m. train, and arrived at Chester about 10 o'clock, and after a ramble through Old Chester, which was much appreciated, they adjourned for lunch, after which the party embarked on board a steamer and enjoyed a voyage down the river Dee and to Eccleston Ferry, and by the kindness of the Duke of Westminster they were allowed to visit Eaton Hall and Park, and take photographs at will, which was thoroughly enjoyed by the members, who arrived home safely by the 10.30 p.m. train, having spent a very pleasant day.

**Dark-Room at Oban.**—Mr. Samuel Lawrence, photographic chemist, 101, George Street, Oban, has a dark-room fitted up, free to customers, and keeps a full stock of plates, chemicals, etc.

**Northern Tasmanian Camera Club.**—The third annual meeting was held on the 20th ult. The President (Mr. R. L. Parker) occupied the chair. After the minutes of the previous meeting had been confirmed, and some correspondence read, three new members were elected—Messrs. E. R. Ash and C. L. Hodgman, of Hobart, and Mr. C. Hart, of Launceston. The secretary then read his report, in which he stated that during the year the progress of the club had been most satisfactory, the number of members on the roll having increased from thirty-six to forty-two. The monthly meetings had been fairly attended, especially those during the latter part of the year, and those at which the optical lantern formed an important feature—at some of the latter meetings a number of visitors, including ladies, had attended. An excursion of the club for practical work in the field took place in November, the scene of operations being Ulverstone and vicinity. Three days were spent in this neighbourhood, there being a good muster of members, and some good and instructive work was accomplished. The thanks of members were heartily due to Messrs. P. C. Maxwell and John Sykes, of Latrobe, as well as to the Ulverstone Improvement Association, whose kindness made the outing all the more enjoyable. One prize competition was held during the year, subject, "Studies of Trees," in which Mr. Wm. Gibson, of Scone, took first certificate, Mr. R. L. Parker second, and Mr. Wm. Aikenhead third. Mr. S. Spurling kindly acted as judge. A second competition was announced to close on June 1st, subject, "Tasmanian Scenery," the prize being a valuable hand-camera, generously presented to the club by Mr. Wm. Gibson. Owing to bad weather very few prints were ready by the above date, and it was decided to postpone the closing of the competition until December 1st. The circulating album had been contributed to better than ever, and competition had been very keen, some of the work sent in being of a high order of merit. Messrs. Gibson, Kermode, Parker, and Styant-Browne had been successful in winning albums. The club was well represented at the Tasmanian Exhibition, a large exhibit being prepared by the united club, while several members exhibited separately. A first award was given to the club, while Dr. Room, Messrs. Parker, Kermode, and Styant-Browne all secured high awards for their exhibits. The club exhibit was afterwards presented to the Victoria Art Gallery. The optical lantern had been in good demand during the year, the loaning of it to members being much appreciated by them. The journals subscribed to by the club had been in good demand, many of the members being very regular in their application for them as a means of information and instruction. The returns of income and expenditure were given in the treasurer's statement, and a credit balance was shown; it was hoped that those members in arrears would forward their subscriptions at an early date. At the conclusion of the reading of the secretary's and treasurer's reports, office-bearers for the ensuing year were balloted for. Competition for the three vacancies on the committee was very keen, there being eight candidates. Four being equal in the first ballot, a second was taken, and the following result was arrived at:—President, Mr. William Gibson, of Scone; Vice-Presidents, Rev. A. H. Champion, Messrs. R. C. Kermode, and R. L. Parker; Hon. Secretary and Treasurer, Mr. F. Styant-Browne; Committee, Messrs. A. C. Bonner, F. Stewart, and J. Sparrow. Heartly votes of thanks were accorded to the retiring President (Mr. R. L. Parker) and to the Secretary (Mr. F. Styant-Browne) for their services during the past year. It was decided that the next album, closing September 1st, should be "General Subjects." A motion proposed by Mr. C. Nickolls was carried—"That members be asked to contribute duplicates prints to form a club album, the committee to select those suitable." A committee was formed to arrange a programme for the next six months. Mr. Gye showed an ingenious instantaneous shutter—his own invention—and an exhibition of lantern-slides closed the evening. The members of the Camera Club have reason to be well satisfied with the growing prosperity of the club, and it is expected that during the coming year the prosperity will still continue to grow, and do good work in fostering artistic instincts, and the love for the scientific and beautiful among its members, and still more spread the knowledge of the charming art-science of photography.

## SOCIETIES' FIXTURES.

- Sept. 2.—LEWISHAM.—"A Shilling's Worth of Photography," Mr. Thos. Child.
- " 2.—RICHMOND.—Informal Meeting.
- " 3.—PEOPLE'S PALACE.—Outing to Wanstead Park.
- " 3.—CROYDON.—Excursion to Zoological Gardens.
- " 3.—WARRINGTON.—Ramble to Higher Walton.
- " 3.—NORTHAMPTONSHIRE.—Excursion to Harleston Firs.
- " 3.—ASHTON-UNDER-LYNE.—Summer Ramble to Chester.
- " 3.—LEYTONSTONE.—Informal meeting.

- Sept. 5.—SOUTH LONDON.—Lantern lecture, "Geo. Tinworth: his Life and Work," Mr. F. W. Edwards.
- " 5.—OXFORD.—Walk.
- " 6.—STAFFORDSHIRE (POTTERIES).—Paper on "Development," Mr. F. C. Powell.
- " 6.—HACKNEY.—Ordinary Meeting.
- " 6.—NORTH LONDON.—Meeting: Comparison of holiday work.
- " 8.—BIRKENHEAD.—Lantern lecture, "Around the Campagna," Mr. Geo. E. Thompson.
- " 9.—RICHMOND.—Discussion, "Improving Faulty Negatives."

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

## RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by TUESDAY MORNING'S POST.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

## QUERIES.

5800. **Printing-in Clouds.**—Can anyone tell "An Amateur" how to print in clouds? The covering over prints with black paper leaves marks between picture and clouds.—AN AMATEUR.

5801. **Foresters' Fate.**—Has any\* brother amateur been successful in taking one or two photographs at the above, and would he oblige me with the loan of negative or print? Address with Editor.—FORESTER.

5802. **Gibraltar.**—Will someone kindly inform me if photography is prohibited at Gibraltar?—W. B. W.

5803. **Developing.**—Will any reader inform me the reason that I am unable to develop my plates as usual? I use Ilford plates and developer according to formula on box. I have been having excellent results from this developer and plates. I use my developer as usual, but I find I cannot get any image to come out on the plate after long exposure and developing. I have added more of ammonia as developer to the plate as usual, but I cannot get a trace, and I have even added the strong liquor of ammonia to the developer without diluting, but none the better. Sometimes after long developing will find a slight trace of the image coming up, but far from printing quality, having tried several times, but found each time the same, having mixed fresh developer from stock, but no better, and should not like to spoil more plates.—WONT GIVE IN.

5804. **Carbonate and Washing Soda.**—Will any reader inform me if there is any difference between carbonate of soda and ordinary common washing soda? Also give formula which is given with Derwent dry plates.—T. JONES.

5805. **Reducing Intensified Negative.**—I have intensified a negative with mercury and ammonia, and made it too dense. Will any reader tell me if I can reduce it without running any risk of spoiling the negative as it is valuable?—SNAPELL.

5806. **Bleaching Prints.**—I find that slight bleaching with copper bromide has an excellent effect in brightening up flat bromide prints. If they are taken out and washed after the process, are any bad effects likely to ensue in the way of staining, fading, etc.—RETSOLE.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## QUERIES UNANSWERED.

- July 15th.—No. 5765.  
 " 22nd.—Nos. 5763, 5768.  
 " 29th.—Nos. 5771, 5778.  
 Aug. 5th.—Nos. 5779, 5780, 5781, 5785, 5788.  
 " 19th.—Nos. 5790, 5791.  
 " 26th.—Nos. 5794, 5796, 5797, 5798, 5799.

## ANSWERS.

5795. **Copying.**—Prints should be placed opposite a window, and camera placed in front of it, and a black or non-actinic curtain should be hung in front of the camera so as to exclude all but the top and side lights.—INQUISITIVE.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S post if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

VERAS.—The yellow stains are due, we think, to some dirt which has accidentally touched the film. You will find on another page some notes on this paper, and we should advise the combined bath suggested on page 22, July 8. If you ever use encaustic paste, a little rubbed on the glass will help you, or make the following:—

Yellow wax	..	..	..	12 gr.
resin	..	..	..	36 "
Ether	..	..	..	2 oz.

Melt the wax, add the resin and ether, pour a little of this on to the glass, rub all over and polish, and you will find it very easy to strip.

GRAHAM HARVEY.—Many thanks for your notes, which will duly appear. We shall be very glad to have others.

R. KENSEY HORNE.—Many thanks for cutting, which appears.

CARAPACHAY.—We will place the subject of your letter before a maker, and write you.

RAPID.—The shutters you name are all on totally different principles, and can therefore hardly be compared. We should advise the Thornton-Pickard.

REFLECTOR.—(1) The image reflected by M on to ground-glass will be the true image as thrown on P. (2) In practice you may disregard the thickness of the glass; on the other hand, theoretically, the two surfaces, the glass and the silver, should cause duplicate or fuzzy outlines. We have used a camera made on this principle for over two years, and never found any difficulty from the double reflection.

LIONEL THIRKELL.—The camera you name is an efficient instrument, and capable of turning out good work.

BOTANY BAY.—The most satisfactory method of washing films is to enclose them in light network frames, as sold by Adams and Co., 26, Charing Cross Road, in their "Club" washer.

EIKENOGEN.—(1) A very pleasing soft print, with distance well rendered. (2) Spoiled by the white marks in the centre, and it would have been preferable to have taken the bridge more on the silt so as to include it all. (3) Under-printed, and wants clouds. (4) Ditto. (5) Under-printed, and the post is not artistic. (6) A great deal too black and heavy; the most artistic so far. (7) Good. (8) The halation at the top spoils this; it wants rubbing down, and print a little too patchy in the foreground. (9) Flat and poor. (10) Very much under-printed. (11) Wants clouds, and your sky line runs up. (12) We cannot make anything of this at all; too flat. (13) Too flat, otherwise a nice little bit. The position of the prints in our competition would depend a good deal on the other work sent in, but with a little more care in printing, etc., one or two should be in class I.

T. HEADWORTH.—Obtain a piece of brass tubing, and mount the lenses with their concave surfaces facing one another, 1 in. apart, place the stop midway. It is really a job for an optician, and at best the lens will be only a makeshift.

BLANCHE.—If you are satisfied with the tone obtained from the combined bath, and do not use the same too long, you need not use the supplementary fixing bath, but your fault lies in not washing thoroughly after the combined bath.

H. I. C.—(1) The only thing to try is a very weak and acid solution of chloride of lime, but first try letting the cambric soak in a weak solution of alum and hydrochloric acid. (2) Transparency frames may be obtained from almost any dealers. Fallowfield, Adams, Pigott, Houghton, etc. (3) Use the largest stop which will give satisfactory sharpness of definition of detail on the screen. In developing, reduce the hydroquinone and increase the quantity of water.

G. H. SAICH.—We know of no apparatus which answers your requirements, but write more fully and let us know what size you want to enlarge from and to.

QUEEN HOTEL, CHESTER.—The formal lines of the masts are not very artistic, but with suitable clouds printed in this could be improved. We certainly do not like the tone of your print, and you would get a softer and more pleasing result by printing on a slightly rough surface.

LEXINGTON.—Is the paper new or old? See article by Mr. Howson in this issue.

R. E. S. L.—Statues would not be admissible as figure-study. Competitors are only allowed to enter one class.

PHOTO.—The prints would be criticised this year.

J. G. ROBINSON.—The lens would probably enlarge up to 8½ by 6½ well.

W. E. ISON.—Send two unmounted prints, and 1s. 6d. to Stationers' Hall, Ludgate Hill, E.C., and they will copyright it for you.

RUSHALLITE.—We will consider your proposal, though we do not think it feasible, nor is founded on a fair basis. Size has nothing whatever to do with the awarding of medals.

NEMO.—(1) The salt does not decompose by keeping, only becomes deliquescent. (2) When the salt is bought, it should be immediately made into a solution of known strength. (3) No, we cannot recommend the borax bath. See the note on this paper in this issue, and try the bicarbonate bath there suggested.

W. P. T.—You have touched the paper with fingers contaminated with pyro or iron, thus causing the stains.

A. G. JEWITT.—Depth of focus is dependent on the aperture of diaphragm and focal length, and practically all lenses working at same aperture and focal length have same depth of focus. The new Concentric lens is rapid enough for shutter work in a bright light, but we should prefer one of the Universal symmetricals for this purpose. The statement that the U. S. works at twice the rapidity of the R. S. means that at full aperture the U. S. works at f/5.6, and the R. S. at f/8, and the exposures would therefore be as 31:3 : 64, or as 1:2. If you want great depth of focus you must have a lens of short focus. Write again if necessary.

TONING.—You will find on page 22 of our issue of July 8th, a very good formula for a combined bath.

## Sale and Exchange

## RULES.

**CHARGE.**—Twelve words or less for Fourpence.

Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the AMATEUR PHOTOGRAPHER, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques or Postal Orders, made payable to Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 8d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the EDITOR, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C., who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

**Bargains in Cameras and Sets.**—Giving up photography. I want to dispose of my complete outfit, consisting of Hinton's Practical camera, half-plate size, one of the best and strongest I ever saw, and three double slides, a Ross whole-plate portable symmetrical lens, a Swift's whole-plate rapid Paragon lens, a really splendid lens, a London Stereoscopic rapid landscape lens, whole-plate, Black Band series, a Thornton-Pickard time and instantaneous shutter, 3½ in. hood,

a Decoudun's photometer, an Ashford's patent folding stand to take whole-plate, the whole contained in a leather case and warranted as good as new; will sell separately if wanted; approval willingly on deposit at office of this paper. The real value of the whole is £25; I will, however, sacrifice for £20, or offers within reason; quite sufficient to start a man in business.—Apply, B., c/o Rev. J. Beck, Liberal Club, Saffron Walden.

S. Dalby Smith, St. Thomas Street, Weymouth, offers the whole of his kit at rare bargain to clear. Almost new whole-plate camera, every possible movement, best make, with one double dark slide, 65s.; finest quality whole-plate rapid rectilinear lens, fitted with L'Automatique shutter, 60s.; half-plate camera, every movement, with six double dark slides (mahogany), 70s.; half-plate rapid rectilinear lens, finest quality, 25s.; first class three-fold tripod, cost 21s., as new, 15s.; also dozens of quarter, half, and whole plate negatives of Weymouth and Dorset; also very fine 10 by 8 negatives of exterior, interior, and interiors of Truro Cathedral; all cheap.

Half-plate long-extension camera, as new, swing-back, rising front, reversing frame, rack and pinion, double slide, instantaneous lens, revolving stops, instantaneous revolving shutter, cost 175s., price £75. 6d.; photo lens by Chadburn Bros., cost 125s., price 45s. 6d.; half-plate French combination lens, cost 45s., price 30s.; cabinet burnisher without lamp, 9s.; pair 8 in. condensers, not been used, cost 110s., price 70s.; background (snow scene), cost 45s., price 10s.; studio stand, 7s.; tripod legs, 5s.; changing bag, 5s.; approval.—P. Linley, 322, Albert Road, Hesley, Sheffield.

**Cameras, etc.**—Middlemiss' Criterion 10 by 8; camera, three slides, in perfect condition, price £5 approval; deposit.—Norrington, Abbotshfield, Plymouth.

Half-plate camera and tripod, very cheap.—T. W. Birdsall, Victoria Street, Barnsley.

Lancaster's International camera, dark slide, three metal slides, adapter, tripod, velvet-lined box, 55s.—E. H., 44, Wandle Road, Wandsworth Common.

**Cameras, Lenses, etc.**—London-made high-class half-plate double extension camera, best leather bellows, reversing back, every necessary movement, one double slide, 47s. 6d.; very finest half-plate extra-rapid rectilinear lens, exquisite definition, Waterhouse diaphragms, 22s. 6d.; great bargains; approval.—Cyclist, 8, Kenilworth Road, Willesden Lane, London, N.W.

A bargain. Lancaster's half-plate latest pattern Instantograph, complete, fitted with Optimus R.R. lens, splendid condition, cash 60s.—Harding, 59, Margate Road, Southsea.

Modern half-plate camera, all improvements, double slide, and rectilinear lens, only used few times, 42s. 6d.—M. Newhouse, 20, Victoria Terrace, Lancaster.

**Enlarging Apparatus.**—Daylight enlarging apparatus, 12 by 10, price £2.—H., 36, Spencer Square, Ruzsgate.

**Exposure Meter.**—Watkins' exposure meter, good as new, 9s.—St. Lucy's Cottage, Kingsholm, Gloucester.

**Ferrotypes Materials.**—Six dozen 3½ by 3½ ferrotypes frames, brasses, and glasses, 19 3½ by 4½ frames only, 86 cut out envelopes, 50 4½ by 3½ brasses, 58 flat oval brasses, 4½ by 3½, 12 odd brasses, 28 ferrotypes plates, 2½ by 3½, and 46 ferrotypes plates, 4½ by 3½, all new. What offers? Cash or exchange.—Saindon, 134, Queen's Road, Watford.

**Hand-Cameras, etc.**—Hand-camera, Samuel's small size, 30s. when new, in good condition; stand for same; also over 150 copies AMATEUR PHOTOGRAPHER. What offers?—Richardson, North Elphinstone, Tranent, N.B.

5 by 4 hand-camera with R.R. lens, finders, dark slide, rollholder, and spool for 48 exposures, price £3; deposit.—E. B., 82, Umfreville Road, Harringay Park, N.

Lancaster's Omnigraph hand-camera, in good condition, cost 25s., 12s. 6d. complete with changing box.—Reinspach, Langham Hotel, London, W.

Underwood's hand-camera, holds 12 quarter plates, quite new, cost 25s., will take 25s.—Lloyd, 2, Rupert Street, Leman Street, Whitechapel.

Hand-camera (Houghton's Automatic), carries 12 quarter-plates, Thornton-Pickard shutter, automatic changer, rapid rectilinear lens, compact instrument, 9½ by 5½ by 4½, has done good work, price £4 10s.—J. B. Hartness, Lauriston House, Ceylon Place, Eastbourne.

**Lenses, etc.**—Pair of Grubb's stereo lenses, in excellent condition, sent for £2, original price £4.—Evers, Faversham, Kent.

Portrait lens, half-plate, by Watson and Son, £2, cost £5, equal to new; also several tripods, equal to n.w. at half-price.—Sprague, 35, Darnley Road, Hackney.

Wray's 5 by 4 R.R. lens, iris, and Caldwell shutter, specially built for instantaneous work, tested, highest speed 1-150th second, also time, cost 105s., take 68s., or take in part exchange Wray's 5 by 4 R.R. hand-camera, iris lens.—Richardson, architect, Wakefield.

For sale half-plate R.R. lens, by Robinson, Oxford Street, 25s., cost 37s. 6d.; Funnell's time and instantaneous shutter, fit 2½ in. hood, 20s., cost 30s., new this year; six half-plate film carriers, 6d. each; four quarter-plate ditto, 4d. each, as new; Tylar's plate washer (tank with half and quarter-plate folding racks), 3s. 6d.; and Tylar's Aquapose washer, print

tray only, 3s.; half-plate single landscape lens, 5s.—31, St. Maur Road, Fulham.

Grubb's C2 portrait lens, 10 by 8, cost £16, sell £5; Burr's 12 by 10 W.A., cost £5, sell £3, as new; Optimus rapid euryscope, 7 by 5, cost 94s. 6d., sell 60s., perfect; Lancaster's Instanto, three metal slides, R.R. lens and stand, cost £5 10s., sell 70s.—Parby, Cradock Street, Swansea.

Ross' 10 by 8 portrait lens, with Waterhouse diaphragms, perfect condition.—Robinson, 7, Northgate, Darlington.

Half R.R. lens by Sands and Hunter, perfect, £1, cost double; quarter camera, lens, slide, stand, 9s.; four trays, two baths, roller, lamp, books, etc., 5s.—H. Locke, 7, Sedgwick Road, Leyton, Essex.

**Negatives.**—Fifty quarter-plate instantaneous negatives (views of London), suitable for making lantern slides, 1s. each; specimen and list, 1s. 3d.—John Stabb, 154, Queen's Road, Baywater.

**Rollholder.**—For sale, Eastman rollholder, whole-plate, good order, 45s.—G. E. Galbraith, Gladstone Place, Stirling.

**Sets.**—Underwood's 1892 half-plate Instanto set, good as new, only 68s.—Ricketts, Cheltenham House, Stroud.

Half Instantograph camera, lens, shutter, three metal slides, and stand, 67s. 6d.; approval.—Thomas, 1, Grugos Terrace, Port Talbot.

Lancaster's quarter-plate Instantograph, fitted with Optimus rapid rectilinear lens, three double dark slides, and three-fold tripod, quite new, leather case, stops, cost over £5 5s., will take £2 10s.—Miss Forrest, 34, Sandgate Road, Folkestone.

Half-plate camera, double extension, reversing back, all movements, tripod, R.R. lenses, instantaneous shutter, view finder, etc., £6.—H. Wells, Bookseller, Norwich.

Lancaster's brass-bound 1891 half-plate Instantograph, double slide, lens, changing box, Thornton-Pickard time and instantaneous shutter, leather case, lock and strap, Tylar's exposure meter, price £4.—H., 36, Spencer Square, Ramsgate.

Rough 5 by 4 camera, changing back for 12 plates, three double slides, leather case, £4; Ross' whole-plate rapid symmetrical, £4 10s.; Dallmeyer W. A. landscape, whole plate, £3; Meagher whole-plate camera, three slides and stand, £4 10s.; two Wray's 5 by 4 R.R., paired by maker, £4; all as new; £18 the lot.—Rev. J. A. Lloyd, Mere Vicarage, Wilts.

Underwood's half-plate Instanto set, complete, cost £4 4s. a month ago, will sacrifice for £2 17s. 6d.—Photo, 83, Crosby Street, Maryport.

To be sold, a 12 by 10 photographic camera by the Stereoscopic Company, with three lenses, three dark slides, and instantaneous shutter, in leather case, complete, only used a few times, with stand; also complete set of developing necessities in leather case.—Apply to W. F., Hill House, Crowhurst, Battle, Sussex.

**Sundries.**—AMATEUR PHOTOGRAPHER, 9 volumes, vols. 6 to 14, unbound, clean, and complete, any reasonable offer, cash.—Sorensen, 20, Porteus Road, Harrow Road, W.

Model marine copper tubular boiler, high class, £6 10s.—Burt, 67, Forest Road, Dalston.

Lathe, 2½ centers, 3ft. bed, £2 10s.—Burt, 67, Forest Road, Dalston.

Ancient model gun frigate, suit captain, £10.—Burt, 67, Forest Road, Dalston.

**Tripod.**—Whole-plate two-fold tripod, new, perfectly rigid, 8s. 6d.—309, Liverpool Road.

## WANTED.

**Cameras, etc.**—Anyone having any quarter Lancaster's camera (Instantograph preferred) for sale or exchange, send their address with particulars to O. H. Medley, Heaton Chapel.

Wanted, quarter-plate double extension Kinear-shape bellows camera, with turntable and legs, two or more double slides, good maker, cheap for cash; approval; deposit.—W. Clare, Malvern Wells.

**Hand-camera, etc.**—Wanted, high-class hand-camera for cash.—c/o 23, Adelaide Street, Blackpool.

**Lenses, etc.**—Wanted, cheap for cash, good 5 by 4 wide-angle rectilinear lens; approval; deposit.—Wiseman, Painswick, Glos.

**Sundries.**—Will the gentleman who took photo of a white yacht off Gorleston Pier on 12th inst. kindly send copy to J. F. Palmer, Ewell Road, Surbiton?

It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.

**Bargains in Hand Cameras.**—Optimus magazine hand-camera, covered leather, carries 12 quarter-plates, finest Optimus rapid rectilinear lens, two finders, shutter, etc., as new, take £5 5s.; Talmer hand-camera, carries 12 plates, fine lens, two large finders, time and instantaneous shutters, as new, take 65s.; Swinden and Earp hand-cameras, carries 20 quarter-plates, fitted Taylor and Hobson's best rapid rectilinear lens, roller-blind shutters and case, as new, £6 15s.; Steinheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take

£4 10s., cost £10 10s.; Optimus detective camera, by Perken, Son, and Rayment, Optimus rapid rectilinear lens, carries six ¼-plates, covered black leather, take £4 4s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 15s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, take 27s. 6d.; Griffiths' best quality hand-camera, carries six ¼-plates, two sunk finders, good lens, pneumatic shutter, take 30s., cost 42s.; quite new, all above are warranted as described. On view, City Sale and Exchange Rooms, 54, Lime Street, corner of Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus of every description bought, sold, or taken in exchange. Inspection invited.

**Bargains in Cameras and Sets.**—15 by 12 double extension camera, leather bellows, rising and falling front, wide angle movement, fitted three double slides, as new, take £8 8s.; 12 by 10 camera, double extension leather bellows, wide-angle movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide, changing box, for 24 plates, also changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; half-plate 1892 Instantograph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, and folding stand, £5 17s. 6d.; 1891 Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Bargains in Lenses.**—15 by 12 Lancaster's rapid rectigraph lens, Silver Ring, iris stops, grand definition, take £5 17s. 6d., quite new; 10 by 8 Lancaster's rectigraph lens, Silver Ring, iris stops, as new, £3 7s. 6d.; whole-plate portrait lens, rack focussing, Waterhouse stops, works f/6, take 68s.; whole-plate True-view lens by Charterhouse Stores, iris stops, movable hood, quite new, take 65s.; 8 by 5 Ross' actinic doublet, rotating stops, 6 in. focus, quite new, latest pattern, take 60s.; 8½ by 6½ Ross' rapid symmetrical, Waterhouse stops, grand definition, as new, £4 12s. 6d.; half-plate Ross' portable symmetrical, rotating stops, 4 in. focus, finest order, 45s.; quarter-plate Continental wide angle rapid rectilinear, rotating stops, as new, 25s.; half-plate wide angle, by Morley and Cooper, rotating stops, as new, 27s. 6d.; half-plate wide angle, by Lancaster, 10s. 6d.; half-plate Ross' rapid symmetrical lens, as new, movable hood, Waterhouse stops, take £3 17s. 6d.; Mayfield's 7 by 5 rapid rectilinear, Waterhouse stops, covers well, 32s. 6d.; Wray's landscape, casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, £3 17s. 6d.; quarter-plate portrait lens, rack focussing, a really good article, take 10s. 6d.; quarter-plate Optimus rapid rectilinear by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

**RICHARDS' Patent Corners**, for mounting photos, prints, scraps, etc., in albums, scrap books, and mounts; clean, convenient, ornamental, self-contained and always handy. Ready gummed, price 1s. the box or by post 1s. 1½d.—F. Watson, 17, Dartmouth Street, Westminster, S.W.

**IMPORTANT TO AMATEURS.**—Negatives skilfully Retouched, Printed in silver, gelatin-chloride, etc., and Enlarged. Also Developing, Copying, etc.—Terms strictly moderate.—Address, Wilfred Emery, 24, South Street, Baker Street, W.

## OUR VIEWS.

"To hold as 'twere the mirror up to nature,"—*Shakespeare*.

The Editor is "At Home" on Monday Afternoons from 2 till 5 o'clock, and will gladly give advice upon all photographic matters; and on Thursday Mornings to Members of the Trade, etc, from 10 till 1 o'clock.

**OUR VIEWS.**—A New Chemical Name—Photography and Royalty—A Photographic Joke—A New Use for Photography—A Thief Detector—An Early Lens—The Queen's Dolls—The P.S.G.B. Exhibition—Photographs of the Year—The Camera Club Winter Session—A New Exhibition—Decease of the East Southsea Society—East London Society's Exhibition—A New Field for Photographers—The Discovery of the Ark—Photographic Spies—Notice—Mr. S. W. Burnham.

**LETTERS.**—Exposure for Interiors (W. H. H.)—Gloucester (Wilkinson)—New Tones on Chloride Paper (Heath)—Waste Material (Howes)—A Question (E. C.)—Society for Forest Gate (Wilton).

**ARTICLES.**—Photographic Procedure (Wall)—General and Photographic Chemistry (Conrad)—How to Make a Set of Photographic Apparatus (H. J.)—Harmonising Harsh Negatives (McIntosh)—Toning of Chloride Prints—Photography in Geology.

**HOLIDAY RESORTS.**—County Antrim.

**SOCIETY MEETINGS.**—Aberdeen—Great Yarmouth—Hackney—Putney—S. Manchester—Warrington.

**EDITORIAL DEPARTMENT.**—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

### TERMS OF SUBSCRIPTION—

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	" 6s. 6d.....	" 12s. 0d.
OUT OF POSTAL UNION ..	" 7s. 9d.....	" 15s. 8d.

**TRADE ADVERTISEMENTS** are received up to Tuesday morning.

**PUBLISHING DEPARTMENT.**—All letters containing Subscriptions, Orders, Remittances, SALE and EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZELL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of *Three Words for One Penny*) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition, No. 40.—  
"PORTRAITURE AND FIGURE STUDY." Latest day, Sept. 19th.—  
Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, October 14th.)

THE tendency of the present age is to hurry and scurry as much as possible, and even photographers seem to think that life is too short to pronounce certain words in full, and "pyro" and "hypo" are far more often used than the full names. To many, too, chemical and even some photographic terms are a stumbling-block. The word denoting the latest colouring matter however, is even worse than anything photography can show, and few could, we think, pronounce it the first time of reading. The word is tetramethyltriimidodiphenyl-methyl-oxytolylmethane, by no means a bad little mouthful. Certainly photographers have much to be thankful for.

PHOTOGRAPHY is now stated to be the craze of Royalty and the upper circles. Our own Princess of Wales has long been a devotee, and there has lately been on show in Stockholm an exhibition of Egyptian photographs taken by the Crown Princess of Sweden and Norway. The Queen of the Belgians has also been inoculated with the mania, and is taking lessons from the best men of Brussels.

CERTAINLY a great deal of the popularity of photography is due to the introduction of hand-cameras, and so universal have they become, that one meets them everywhere and in all hands. So generally has this become recognised that even the professional jokist takes the hand-camera as a promising subject, and the latest on this point is the following:—

BROWN: And so that young woman is going to bring a suit of breach of promise against you? Did you ever write any compromising letters to her?

GREEN: Never wrote a letter of any kind.

BROWN: Then you're all right. She can't prove anything.

GREEN: Can't she? Whenever I called she had her brother take snap shots of us with his Kodak."

ANOTHER side is the use made of photography for different purposes, but the following clipping from *Truth* certainly has its comic side:—

"The Rev. A. E. Johnson, minister of the Baptist Providence Chapel at Penknapp, near Westbury, advertised in the local papers that there would be baptising by him last Sunday morning in Stormalore Water, a neighbouring lake, and he invited the attendance of photographers."

TURNING from the comic to the more serious side, photography has been of considerable assistance to justice. Defaulters and criminals in many cases owe their arrest to

having at some unfortunate moment had their photograph taken, which, although in the first instance merely a love token, has later become the instrument of their arrest. The following thief detector, which appears in an American paper, is certainly a novel application. A cigar merchant had for some time missed cigars from his glass show-case, and, unable to detect the thieves, he fixed up a flash-light apparatus which was connected with the show-case by the wires of a battery, so that on opening the show-case the circuit was closed, the camera shutter opened, a flash-light ignited, and the plate exposed, catching two boys in the act of opening the case. Obviously the applications of this plan are very numerous, and it adds yet another terror to the life of the honest burglar.

It has always been an undecided question as to when lenses were first made. Although Sir David Brewster states that a piece of rock crystal of plano-convex form now in the British Museum in the Assyrian section, and the date of which is about 720 B.C., was designed for magnifying, we have no satisfactory proof of it. Mr. H. G. Hanks, in a paper before the Astronomical Society of the Pacific, quoted the following extract from the works of Henry Cornelius Agrippa, who lived in the early part of the sixteenth century:—"So we read, as Coelius in his ancient writings relates, that one Hostius, a person of an obscure life, made a sort of glass that made the object seem far greater than it was; so that one finger should seem to exceed the whole arm both in bigness and thickness." The exact date of Coelius is uncertain, but there is evidence that he lived prior to Livy, B.C. 59, and therefore Hostius was still earlier.

The September number of the *Strand Magazine* will contain reproductions from photographs of a large number of dolls which were dressed by the Queen when she was a girl. These little beings have been stowed away in Buckingham Palace, whence they were unearthed by Sir Henry Ponsonby. They have been photographed by Messrs. Elliott and Fry, and Her Majesty has herself corrected and revised the manuscript referring to them.

We are requested by the Secretary of the Photographic Society of Great Britain to remind our readers that the Exhibition will open on Monday, 26th inst., and remain open until November 10th. The usual conversation will be held on Saturday, September 24th. As heretofore, medals will be awarded for artistic, technical, and scientific excellence of prints and apparatus, the judges being Messrs. Debenham, W. England, F. P. Cembrano, jun., F. Hollyer, and J. Traill Taylor, with Captain Abney and Andrew Pringle as scientific experts. The Assistant Secretary of the Society will forward entry forms, and the latest date for sending in exhibits is the 14th inst., at 5A, Pall Mall East.

It is well known that there will be some notable abstentions this year; many of our best workers will not be represented. But, as suggested the other day to us, this will give some of the younger workers a chance to show us that they can and will do equally as good work as the older hands. Be that as it may, the Pall Mall Exhibition is looked forward to with great interest and curiosity.

The well-deserved success of the 1891 "Photographs of the Year" encourages our publishers to issue another portfolio containing the pictures of 1892. We cannot, of course, make any announcement as to the particular pictures which will be reproduced, nor the date of publication, but the

selection has been placed in the hands of a very artistic worker in photography, and we are sure that this year's issue will not be inferior to last. It will contain twelve reproductions in Woodbury gravure or other permanent process, mounted on india-tint plate-sunk mounts. The pictures as last year will be accompanied by letterpress, which will form a valuable critique upon the Exhibition pictures other than those reproduced. The book will be published at half a guinea, but a limited number will be sold to subscribers at 7s. 6d.

THE winter session of the Camera Club will be opened as usual by a smoking concert and soiree on Monday, October 10th. Members of the club will find the rooms at their soiree very artistically decorated, this work not having been done before, as the walls were not considered dry enough.

It has been usual to inaugurate the winter session of the Camera Club by a "one man" exhibition, and although this series has been exceedingly popular, the powers that be have made an innovation which we unhesitatingly say will be very popular; they intend to hold a special invitation exhibition, which will include specimens of the recent work of every leading worker in photography.

WE regret to note that the East Southsea Photographic Society has died a lingering death from inanition.

THE East London Photographic Society will hold an open class competition, at their head-quarters, Shoreditch Town Hall, of which the following are the main conditions, the subject being "General Photography":—

(1) Open to ladies and gentlemen. One print only to be sent in this competition. Entrance fee, 1s. Prize pictures shall become the property of the East London Photographic Society. (2) The work must be entirely that of an amateur photographer—exposure, development, retouching, printing, toning, and mounting. (3) Photographs may be printed by any process, or on any paper, but must not be printed on opal or mounted in optical contact on glass, or from an enlarged negative. (4) Prints must be sent in not later than October 18th, 1892. (5) No name must appear on the print, but the title must be legibly written on the front of the mount, and the entry-form duly filled up and enclosed. (6) Prints having been awarded a prize in any previous competition, will not be eligible for competition. (7) Prizes: 1st, silver medal; 2nd, bronze medal; 3rd, certificate. (8) Unsuccessful prints will be returned if accompanied with stamps.

All photographs to be endorsed E. L. P. S., "Open Class Competition," and addressed to Mr. M. A. Wilkinson, 28, Shacklewell Lane, Kingsland, London, N.E., from whom entry forms, etc., may be obtained.

THE extension of the Metropolitan Railway to Aylesbury has opened up a new and easily accessible field to amateurs. Wendover, Aston Clinton, Princes Risborough, Waddesdon and the Vale of Aylesbury will now be the happy rambling ground for photographic societies, on their excursions. Aylesbury is in parts a curious, sleepy old place, though there is plenty of life too here and there, and our publishers' printing works at one end of the town give bustle and life to leafy roads and country lanes.

According to our contemporary *Science Siftings*, the Rev. J. T. Nouri, the Chaldean Archdeacon of Babylon and Jerusalem, has informed the representative of a San Francisco paper that he has actually discovered the remains of Noah's Ark on the top of Mount Ararat. The following is his description:—

"It was in the month of March that we made up our minds that it would be impossible to reach the top in such weather. We must

wait till the snow, or a great deal of it at least, melted. We accordingly went still further below, and remained till April. Then we were abundantly paid for all our labour, for we discovered what I feel sure was the ark, the actual work of Noah. I discovered it myself, being the first to see it. I saw it through a field glass at first, though we got so close to it that it was visible to the eye alone. We had reached a bight over the green grass, and at length in deep snow and over glaciers of probably 16,000 or 16,500 feet and within 1,500 or 2,000 feet of the top. Presently a great object came into view through the glass. The bow and stern were clearly in view, but the centre of it was buried in snow and one side of it had fallen down and was decayed. It stood more than 100 feet high, and was more than 300 yards long. The wood seemed very peculiar. It was dark reddish, almost iron-coloured, and seemed very thick. I saw it perfectly, especially the rear part. It is between 5,000 and 6,000 years old. Would the wood last for that time? Oh, yes. It would not were it not for the snow, but that has preserved it. Were it not for that, constructed even of hard wood as it is, it would have been impossible to last over 2,000 or 3,000 years. As it is, it will be preserved for ages and ages, perhaps 20,000 or 30,000 years."

We have often heard before of the discovery of the ark, the last explorer advancing as a proof the fact that he saw a grease spot where Ham sat down.

But our object in calling attention to this report is to point out how incontestable the statement would be had the venerable archdeacon or one of his party photographed it. One of our readers wishes to know which would be the best plate and light to photograph it in? Unfortunately, we have had no personal experience in this particular line. Can any of our readers oblige with the information?

It is no uncommon thing to find some unfortunate English traveller getting into trouble over photographing in or near fortifications, but at last we are even with the foreigner, for one has been arrested in Brisbane for photographing the forts there.

We should like to know what would prevent anybody from using one of Dallmeyer's telephotographic lenses for this illegal practice? It would be no easy matter to detect and catch a photographic spy who worked a mile or two off.

We wish to draw the attention of our readers to the following announcement:—

In no case will the Proprietors of the AMATEUR PHOTOGRAPHER undertake to buy or sell any goods on commission, nor will they be responsible for the safety of any negatives or prints sent to the Editor of the AMATEUR PHOTOGRAPHER for any purpose whatever, although all reasonable care will be taken of the same.

The Editor claims the right of refusing any print, lantern slide, etc., sent in for competition, without assigning any reason for such refusal.

MR. S. W. BURNHAM who has probably the highest repute of any astronomer as a discoverer of double stars, and who has made of course the application of photography to astronomy his particular study, and has, in his official capacity, as chief assistant to Professor Holden, at the famous Lick University, probably accomplished more in this direction than any one else—is retiring from his post to one more lucrative, if less scientific. We need hardly fear, however, that his invaluable services will be lost to astrophotography, as in his early days Mr. Burnham was a stenographer by day and an astronomer by night. He even once competed in one of our competitions and took a medal. Outside astronomical photography, he is well known in America for his successful instantaneous work.

THE Pendleton Lads' Club will open their Winter Session on or about the 28th inst., with an Arts and Crafts Exhibition, photography being included in one section.

## Letters to the Editor.

### EXPOSURE FOR INTERIORS.

SIR,—Perhaps you can find space for a reply, in a perfectly friendly spirit, to "J. G. P.'s" remarks on my times of exposure. I confess I have often been fairly astonished myself with the good results obtained from very short exposures, which led me to conclude that the tremendously prolonged exposures usually recommended were a survival of the old wet plates, and quite unnecessary now. Here is a somewhat extreme case. On a dull day in March I was photographing in Worcester Cathedral, and taking a view of the choir and King John's tomb. It was so dark that I could scarcely see to focus. I was using iso-chromatic instantaneous plates, and intended to give it half an hour, but the inexorable necessities of railway travelling compelled me to be content with fifteen minutes. As it was such a dark day, I, of course, expected it to be hopelessly under-exposed, but to my surprise it came out very well with full detail. The fact seems to be that there is considerable latitude of exposure in interior work, and the results of over-exposure are not so apparent as in outdoor photography. The longer the exposure the greater the risk of halation, and if ten minutes is sufficient, what need to expose for an hour? I have not seen any nave or choir yet which required so long, except in very dull weather indeed. Winchester and Salisbury are nearly as light as out of doors, and five minutes was quite enough. Ten sufficed at Peterborough, fifteen to twenty at Exeter; and Gloucester, Durham, and Worcester, which I visited on very dull days in March alone, required exposures of forty minutes. Then as to developer: I entirely disagree with the notion that hydroquinone, of necessity, produces either hardness or lack of detail. Some years ago, before this developer was well known, Mr. W. S. Ingall used to write articles in the "Year Book," extolling it for possessing those very qualities of softness and detail for the lack of which it is now condemned. I hold that the fault is with the user. Most of the ready-made developers now sold are much too strong; but the chief fault is with that highly objectionable hydrate of soda now so generally used, because it is quicker in action than the mild carbonates. It is violent and uncertain in action, often fogging the plate and blocking the lights before the shadows are out, besides producing frills and blisters from its highly caustic nature. Discard it, and substitute carbonates of potash and soda; avoid the use of bromides; make up your developer weak in hydro (just as you would with pyro for the same work), and the result should be quite equal to those of our old but very dirty friend, pyro. Good results depend greatly on the way a developer is used. Pyro will be quite as hard and unsatisfactory as hydro is supposed to be, if it is used as improperly as hydro very often is. I am very slow in taking up a new developer. I stuck to pyro, long after hydro had become a mania; but when I was at last persuaded to try it I was converted at once, and have never used any other, and still like it as well as ever, now that the mania seems to be over. I think glass plates are quite unsuitable for interior work. Backing is a "tedious and dirty business, involving infinite trouble" (*vide* AMATEUR PHOTOGRAPHER of this week), and of very doubtful utility. Films show no halation under ordinary circumstances, but sometimes both films—and even Eastman negative paper—had this annoying defect nearly as badly as glass; so that it seems to be a real phenomenon; at least, in some cases, due, I believe, to aberration, and quite independent of the support used.

I enclose some prints from my negatives for your inspection, and leave it to your judgment whether they are either under-exposed or deficient in detail. Of course, I do not mean that my times apply in all conditions of light, weather, or time of year. There is always room for discretion in these matters, but they are those which, under the circumstances, I found to be quite sufficient.—Yours, etc.,

W. H. H.

[Only two out of the dozen prints sent by our correspondent show undue hardness in certain portions, and in both these cases they are white pillars—we should say brilliantly illuminated.—EDITOR.]

\* \* \*

### GLOUCESTER.

SIR,—With reference to the account of a visit to this ancient city contained in last week's issue of the AMATEUR PHOTOGRAPHER, I notice that your correspondent omitted to mention

the name of a photographic dealer where plates could be changed, etc. Kindly allow me now to supply this information, which may be useful to your readers.

I have pleasure in stating that Mr. Walwin, chemist and dealer in photographic apparatus, of Southgate-street, Gloucester, affords ready access to his dark-room for a trifling fee, or customers may have the use of same free. Mr. Walwin is also Secretary of the local society, and a most courteous gentleman.—Yours faithfully,

E. R. WILKINSON.

\* \* \* \*

#### NEW TONES ON CHLORIDE PAPER.

SIR,—With reference to the now almost universal chloride printing-out papers, I am not aware if it is generally known that green and blue tones are producible upon them. A very pretty green suitable for landscapes pure and simple is easily obtained, and greeny-blue tones very effective for moonlight effects by same formula. It is obtainable by fixing prints direct from frame, and toning with uranium and ferricyanide of potash, a good washing, and flooding with a weak solution of perchloride of iron. This treatment I have seen recommended for bromide, and tried it on chloride paper, upon which it has the same effect. It may be information to some that these papers can be toned *after fixing* with uranium.

#### FORMULA.

Uranium nitrate .. .. .	4 gr.
Ferricyanide potash .. .. .	4 "
Vinegar or acetic acid .. .. .	A few drops.
Water .. .. .	8 oz.

Dissolve ferricyanide in water, add half a drachm of acetic acid, then the uranium nitrate.

After washing, which should not be too vigorous, put three or four drops of perchloride of iron into 2 oz. water, and flood the print. This tones through a brownish-green to green, and afterwards blue-green.—Yours, etc.,

CHAS. E. HEATH.

\* \* \* \*

#### WASTE MATERIAL.

SIR,—This is indeed a "large" order in connection with photography; and without doubt, great benefits would be derived from it. I myself have occasion at times to cut up a large number of sheets, which will forthwith go into the sack, but I shall take the precaution to have it weighed. Then again I have the toning, washing, and fixing baths; these I shall put in carboys. These also shall be weighed, and I think that if all amateurs and professionals will do likewise, and send them up to you—"they must be sent to you as per letter"—you might possibly find enough work to keep the unemployed in full swing. At anyrate, Pickford and Co. would be able to treble their staff, and you could call in the contractors to pitch up a block of houses. Of course, I shall expect my share of the profits. A first-class outfit will suit me at present (10 by 8), and I would only be too pleased to offer my services on salary and commission, but I would prefer a tram car, with rails around towns, country, and coast.

Mr. Editor, here is your chance of immortalising your name, the greatest benefactor of the universe. Here is the solving of the social question. Do, I beg of you, charter your dust carts, hasten your contractors, issue special orders for bonfires on Hampstead Heath. Cry aloud for more lifeboats, and your fame is assured but above all do not forget my outfit.—Yours, etc.,

H. HOWES.

\* \* \* \*

#### A QUESTION.

SIR,—Pardon your servant in this thing, but the desire has come upon me to write you a line, being an amateur of the amateurs, with a barrow load of used up plates to testify, to which I often look with a heavy heart, and sometimes wonder if the day will ever come when I shall realise any of those feelings which spring from conquest. Longfellow reminds us that—

We should act that each to-morrow  
Finds us further than to-day.

This I want to do, but, for a working man, is the game worth the candle?—Yours, etc.,

R. C.

[Our pardon is readily granted, and if our correspondent will send up some prints with what they are intended to represent written on the back, so that we may not offend him by criticising the portrait of a long-eared quadruped as his, we or our readers may be able to help him.—EDITOR.]

#### SOCIETY FOR FOREST GATE.

SIR,—I know of no photographic club in the districts of Stratford and Forest Gate, and if any of your readers who reside near this way would like to have one, and join it, I should be glad if they will communicate with me on the subject.—Yours, etc.,

S. L. WILTON,

Longmoor Villa, Romford Road,  
Stratford, E., Sept. 5th, 1892.

## Photographic Procedure.

By E. J. WALL,

(Author of the "Dictionary of Photography.")

#### SECTION VI.

#### DEVELOPERS AND DEVELOPMENT.

(Continued from page 136.)

*Pyro and Ammonia.*—Probably this has been and is still the developer most used, especially by professional photographers, and therefore a somewhat full consideration of its use will not be amiss.

In the first place we may use our pyro dry, and measure or weigh out the quantity for each plate, but it is far preferable to keep the same in a stock solution of given strength, say, 10 per cent., by which means we may measure out the required quantity of solution at once, more conveniently than weighing or guessing. We have already spoken of the addition of certain substances to the pyro solution which may act as preservatives and prevent the rapid deterioration of the solution from absorption of atmospheric oxygen, and as pyro is more liable to oxidation when in alkaline solution, an acid is frequently used as a preservative. A stock solution compounded on these lines may be made as follows:—

Pyrogallol .. .. .	1 oz.*
Nitric acid .. .. .	30 drops.
Distilled water to .. .. .	9 oz.

or

Pyrogallol .. .. .	1 oz.
Citric acid .. .. .	40 gr.
Distilled water, to .. .. .	9 oz.

These solutions will not keep very long without some slight colouration ensuing, but this need not be taken much notice of. If kept in the dark and well stoppered, they may be constantly opened and yet keep good for about six months.

*The Restrainer.*—This, with every form of developer, is, as we have already stated, a soluble bromide, usually of potassium or ammonium, and although numerous questions and statements have been made upon the subject, there exists, so far as I know of, no authoritative statement as to the different powers of these two salts. If, as has been stated, their restraining power is dependent on the amount of bromide they contain, then the ammonium salt should be the stronger, but in practice they may be considered of equal strength, and a convenient stock solution may be made by dissolving

Ammonium or potassium bromide .. .. .	1 oz.*
In distilled water up to .. .. .	9 "

There is only one point in connection with the question of which to use, that is of any importance, and that is that when ammonium bromide is used with a sulphite or meta-bisulphite, the ammonia is set free, and may and does lead to some curious results sometimes.

*The Accelerator.*—This is also conveniently made in a 10 per cent. solution by adding—

Solution of ammonia (sp. gr. .880) .. .. .	1 oz.
Distilled water .. .. .	9 "

\* 437½ gr. 1 commercial ounce bottle.

Many advise the use of the strong liq. ammonia '880, as it is called, itself, but this is not advisable, so difficult is this solution to keep of full strength that once opening of the bottle is enough to reduce the strength, and it is also much easier to use a weaker solution in developing, as slight errors in measuring are not of so much moment.

*The Developer proper.*—The quantities of the developer for each given sized plate varies not only with the size, but also with the worker's own ideas, and also with the kind of dish used, some dishes requiring more solution as the plate does not lie flat on the bottom in them.

We may consider, however, that a quarter-plate,  $4\frac{1}{4}$  by  $3\frac{1}{4}$  in., will require  $1\frac{1}{2}$  oz.; a half-plate,  $6\frac{1}{2}$  by  $4\frac{3}{4}$  in., 2 oz.; a whole plate,  $8\frac{1}{2}$  by  $6\frac{1}{2}$  in., 3 oz. Many workers can use less, but it is just as well, especially for beginners, to use the quantities we have given above, as there is less chance of bubbles being formed.

As we shall have to consider the development of a plate, it will simplify matters considerably if we take one given sized plate, such as a half-plate, but as a guide to users of other sizes, we may as well state that a normal developer will contain 3 grains of pyro, 3 grains of bromide, and 3 to 4 drops of ammonia in every ounce. Mr. Bothamley, in a communication to the P.S.G.B., gives the following as a

#### STANDARD PYRO-AMMONIA.

##### A.

Real ammonia, $\text{NH}_3$ .. .. .	5 parts
Ammonium bromide .. .. .	10 "
Water up to .. .. .	1,000 "

##### B.

Pyro .. .. .	10 parts
Water up to .. .. .	1,000 "

Mix in equal volumes immediately before use, and develop for ten minutes in an open dish, with occasional rocking, at 15 deg. C (60 deg. F.).

Let us return, however, to our half-plate. Before taking the plate from the dark-slide, mix your developer, or at least measure out the quantities. We want 2 oz. of developer, and therefore measure out 60 minims of pyro solution, the same quantity of bromide solution, and make up to 2 oz. with water. Measure out 40 minims of ammonia in a separate measure, and for this purpose a graduated minim measure is preferable. Now remove the plate from the dark slide; dust the film well with a soft, flat camel's-hair brush or piece of soft wash leather. Care should be taken that the brush, or wash leather, is not roughly used, as we have seen curious scratches formed in this way, which have considerably puzzled the operator. Lay the plate in the dish, and add 10 minims of ammonia to the diluted pyro solution, and, taking the dish in the left hand, sloping it gently from you, pour the developer over the plate in an even wave, and rock the dish gently, and then examine for the air bubbles. These, as a rule, can be better seen by looking sideways at the dish, and if one is seen it should be immediately broken with the tip of the finger. Many recommend the use of a brush in the developer for the same purpose, but, personally, I do not like the brush, because it is very liable to introduce dust or traces of old oxidised developer. Others again, and I am sorry to say that I am rather fond of this trick, pass the tips of the fingers rapidly over the surface of the plate when wetted by the developer, and, provided the fingers are clean—and they should be—I have never found the slightest harm accrue to anything but the fingers, which sometimes get a little stained by this method.

After gently rocking the plate for about a minute it should be examined to see if there is any sign of an image. For this purpose it is not necessary to lift the plate from

the dish and hold it up to the light. Faint traces of the image can be seen far better by looking down on it. Usually some portion of the high lights will appear first—in a portrait, the cuffs and collars; in a landscape, the sky. As a rule, however, unless the plate has been much over-exposed no sign of the image can be discerned, so pouring another 10 minims of ammonia solution into the measure we pour the developer from the dish back on to the same, and then flood the plate again with the developer. It will be noted that we have suggested adding the developer to the ammonia in the measure—not the ammonia to the developer in the dish. If the latter plan be adopted it might happen that the full strength of the ammonia was exerted in one spot, and a black patch be caused there. Gently rocking the dish, we now watch it for another minute, and probably we shall see faint indications of some portions of the image, then we add another 10 minims of ammonia in the same way as before, and again watch the image, which should now be plainly visible, all—but in some small portions—gaining strength or density, as it is called. If, after allowing development to proceed for another minute or so, there are still some parts of the plate absolutely white, or the image is not dense enough—and this is a point, unfortunately, which experience alone can teach—we then add the remaining quantum of ammonia, and continue as before, till development is finished, when the plate may be well rinsed and fixed.

(To be continued.)

## General and Photographic Chemistry.—VI.

By E. C. CONRAD, F.C.S.

### THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.—(Continued).

#### COMPOUNDS OF NITROGEN WITH HYDROGEN AND OXYGEN.

*Ammonia*,  $\text{NH}_3=17$ .—Weight of a litre at Stp., 0.762 gram. Oc.: In the air and rain water. M.: Largely obtained by the destructive distillation of coal, as in the manufacture of gas; by blowing steam through the ammoniacal liquor produced, ammonia is given off and condensed in dilute vitriol forming ammonium sulphate. It can also be obtained by the direct union of its elements. When any of the compounds of ammonia are heated with the alkaline earths or caustic soda, they are decomposed and their ammonia is given off. Thus ammonium chloride, or sal-ammoniac, gives with lime water, calcium chloride, and ammonia. Eq.:  $2\text{NH}_4\text{Cl} + \text{CaO} = 2\text{H}_2\text{O} + \text{CaCl}_2 + 2\text{NH}_3$ . This reaction takes place slowly at the ordinary temperatures, and rapidly on gently heating. Ammonia being 0.58 times lighter than air, can be collected by upward displacement. P.: Ammonia is a gas at the ordinary temperatures and has a pungent odour, and if inhaled in quantities it has an injurious action on the membranes of the throat. Ammonia gas can be condensed to a liquid by cooling it to  $-40^\circ$  or by a pressure of six atmospheres at  $10^\circ \text{C}$ ., and it freezes to a transparent ice-like mass at  $-75^\circ$ . The gas is feebly combustible, burning with a greenish-yellow flame. By passing the gas through a red-hot tube it is decomposed into its elements. It is extremely soluble in water; at  $20^\circ \text{C}$ . 68 volumes of the gas are absorbed by one volume of water, and at  $0^\circ \text{C}$ . 1,149 volumes. The solutions increase very much in bulk, and the strongest obtainable has a S.G. of 0.88, and freezes at  $-38^\circ$ . The whole of the gas is expelled on boiling. The gas and its solution has a strong alkaline reaction, turning reddened litmus blue, and

neutralizes all acids. Ammonia acts as a metal, forming a series of salts similar to those of potassium and sodium. *Tests*.—Ammonia gas and its solution can be recognised by (1) their characteristic smell, (2) action on litmus paper; (3) giving a white precipitate with solutions of mercuric chloride. Very dilute solution gives a brown colouration with Nessler's solution (a mixture of potassium iodide, mercuric chloride, and caustic potash dissolved in water). *Uses*.—The condensed gas is employed for refrigerating purposes. The solution is used as a reagent, precipitating most metals from their salts as hydrates. With solutions of copper salts it gives a characteristic blue colouration. Ammonia solution readily dissolves silver chloride, silver bromide with difficulty, and silver iodide is insoluble. U. P.: The gas is used to some extent in the manufacture of dry plates and sensitive papers. The solution is used in gelatine bromide emulsion making, in which it forms a salt with silver nitrate,  $\text{AgNO}_3 \cdot 2\text{NH}_3$ . Its most important use is as an accelerator in development with pyrogallol acid; its action is to render the solution of pyro alkaline, and thus increase the dioxidising power of that substance. The strong solution diluted with nine times its volume of water makes a convenient strength. It has been already stated that the Radical  $\text{NH}_3$  unites with acids to form salt.

The principal salts of ammonium are:—

*Ammonium Chloride*, or sal ammoniac,  $\text{NH}_4\text{Cl}=53.5$ .—M.: By leading ammonia gas into hydrochloric acid direct combination takes place. Eq.:  $\text{NH}_3 + \text{HCl} = \text{NH}_4\text{Cl}$ . It is manufactured commercially from the ammoniacal liquor of gasworks by neutralizing with hydrochloric acid and evaporating to dryness, or by subliming the commercial sulphate with common salt. P.: It forms a tough fibrous mass, which can be volatilised without melting. It is soluble in three times its weight of cold water, but only slightly in alcohol, 1 part of the salt requiring 55 of the spirit to dissolve it. The commercial salt usually contains iron, shown by a brown or yellow colour; it can be purified by adding to its solution a little ammonium hydrate ( $\text{NH}_4\text{HO}$ ), filtering off the iron hydrate formed, and neutralising the alkaline filtrate exactly with pure hydrochloric acid. The salt and its solutions do not smell of ammonia, and if pure are colourless. U.: As a reagent. U. P.: In making gelatino-chloride emulsion, in making a strong solution of mercuric chloride for intensification, but principally used for salting albumenised paper.

*Ammonium Bromide*,  $\text{NH}_4\text{Br}=98$ .—M.: By neutralising hydrobromic acid with ammonia. Eq.:  $\text{HBr} + \text{NH}_4\text{HO} = \text{NH}_4\text{Br} + \text{H}_2\text{O}$ . It can also be prepared by many processes of double decomposition, such as the action of a solution of ammonium sulphate on one of potassium bromide. Eq.:  $(\text{NH}_4)_2\text{SO}_4 + 2\text{KBr} = 2\text{NH}_4\text{Br} + \text{K}_2\text{SO}_4$ . P.: It is a fine, nearly white powder, soluble in  $1\frac{1}{2}$  times its weight of water, and also in alcohol. U. P.: Sometimes used in the preparation of gelatino-bromide emulsion, but chiefly employed as a restrainer in alkaline development. The action of the potassium and sodium salts of bromide is the same but their restraining power being in proportion to their atomic weights. Ninety-eight parts of ammonium bromide would be equal in effect to 103 parts of sodium bromide or 119 parts of potassium bromide.

*Ammonium Iodide*,  $\text{NH}_4\text{I}=145$ .—M.: By neutralising hydriodic acid with ammonia. Eq.:  $\text{HI} + \text{NH}_4\text{HO} = \text{NH}_4\text{I} + \text{H}_2\text{O}$ , and evaporating to  $100^\circ\text{C}$ . By the decomposition of ferrous iodide by ammonium carbonate or barium iodide with ammonium sulphate. P.: Obtained as small yellowish crystals, which are deliquescent and acted upon by light. It is very soluble in water and fairly soluble in alcohol. U. P.: Largely used for making iodised collodion.

*Ammonium Nitrate*,  $\text{NH}_4\text{NO}_3=80$ .—M.: By neutralising nitric acid with ammonia or ammonium carbonate. Eq.:

$(\text{NH}_4)_2\text{CO}_3 + 2\text{HNO}_3 = 2\text{NH}_4\text{NO}_3 + \text{H}_2\text{O} + \text{CO}_2$ . P.: Obtained as a semi-crystalline powder usually deliquescent. Soluble in twice its weight of water, the solution of this salt produces cold. U. P.: It is used in the tropics to cool solutions during development, and to prevent frilling.

*Ammonium Sulphide*,  $(\text{NH}_4)_2\text{S}=68$ .—M.: By passing sulphuretted hydrogen gas through ammonia. Eq.:  $\text{H}_2\text{S} + 2\text{NH}_4\text{HO} = (\text{NH}_4)_2\text{S} + 2\text{H}_2\text{O}$ . P.: It is a yellowish liquid of a most disagreeable smell. U.: It is an important reagent in analytical chemistry. U. P.: Used in intensification to blacken the mixture of mercury and silver chlorides produced by the action of mercuric chloride on the metallic silver of the image. Also to precipitate silver from hypo fixing baths.

*Ammonium Sulphocyanate*,  $\text{NH}_4\text{CNS}=76$ .—M.: By boiling powdered sulphur with a solution of ammonium cyanide. P.: It is a compound of sulphocyanic acid and ammonia, and occurs in transparent deliquescent crystals; soluble in its own weight of water. U. P.: Employed for toning gelatino-chloride printing-out papers. It has also been used as a fixing agent instead of hypo, but its higher price, without any corresponding advantages, has prevented its general use.

*Ammonium Carbonate*,  $(\text{NH}_4)_2\text{CO}_3=96$ .—Syn.: Sesquicarbonate of ammonia, sal volatile, smelling salts, etc. M.: Prepared by adding ammonia to one of the acid carbonates. By heating a mixture of sal-ammoniac and chalk. Eq.:  $2\text{NH}_4\text{Cl} + \text{CaCO}_3 = \text{CaCl}_2 + (\text{NH}_4)_2\text{CO}_3$ . It is obtained as a by-product in the manufacture of borax. The commercial compound is often very impure. P.: It is a white solid, smelling strongly of ammonia. Soluble in about three times its own weight of water. U.: As smelling salts. U. P.: It is sometimes used for development.

*Ammonium Citrate*,  $\text{C}_6\text{H}_5(\text{NH}_4)_3\text{O}_7=243$ .—M.: Prepared by neutralising citric acid with ammonia. Eq.:  $\text{C}_6\text{H}_5\text{O}_7 + 3\text{NH}_4\text{HO} = \text{C}_6\text{H}_5(\text{NH}_4)_3\text{O}_7 + 3\text{H}_2\text{O}$ . P.: It is a deliquescent solid. U. P.: As a restrainer in the development of gelatino-chloride dry plates.

*Ammonium Oxalate*,  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ .—M.: By neutralising a solution of oxalic acid with ammonium carbonate. Eq.:  $\text{H}_2\text{C}_2\text{O}_4 + (\text{NH}_4)_2\text{CO}_3 = (\text{NH}_4)_2\text{C}_2\text{O}_4 + \text{CO}_2 + \text{H}_2\text{O}$ . P.: Occurs in fine needle-shaped crystals, soluble in water. U. P.: Used in plantinotype printing paper.

*Ammonium Bichromate*,  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7=252$ .—M.: By neutralising chromic acid with ammonia. P.: Occurs in powder or in orange-coloured crystals, soluble in water. U. P.: Used in photo-mechanical printing. There are a large number of ammonium salts of which the above are the principal ones used in photography. In general chemistry, besides some of the above, ammonium molybdate ( $\text{NH}_4\text{HMoO}_4$ ), used as a test for phosphates, and ammonium sodium phosphate or microcosmic salt ( $\text{NH}_4\text{NaHPO}_4$ ) are the most important.

*Tests*.—All ammonium salts are decomposed with evolution of ammonia when heated with a hydrate of an alkali ( $\text{KHO}$  or  $\text{NaHO}$ ) or alkaline earthy metal. Tartaric acid gives from a concentrated solution of some ammonium salts a white crystalline precipitate. Platinic chloride gives a heavy yellow precipitate if the solution is not too dilute.

(To be continued.)

**Liverpool Camera Club**.—Usual meeting on the 24th ult., Mr. T. Edwards presiding. Samples of the Ilford P.O.P. were handed to the members, and the new Bynoe printing frame was placed upon the table for inspection. Mr. H. Handley then read a most interesting and carefully prepared paper upon "Optics for Amateurs," illustrating it with a number of drawings. The subject being well received, Mr. Handley promised some further remarks upon it at a subsequent meeting.

# How to Make a Set of Photographic Apparatus.

By H. J.

(Continued from page 140.)

## CHAPTER V.

### THE TRIPOD STAND.

COMPARED with the subjects of the previous chapters this will be mere child's play, so that a great many who may not have the necessary skill or pluck to attempt the camera and slides will be able to make the tripod with ease, and as it is (or I always think so) a very expensive piece of apparatus compared with the rest of the kit, I hope to find many of my readers making their own. For this reason, and to cater for all classes as well, I shall describe

FIG. 36.

two kinds of stands. The first one will be very simple and require scarcely any fittings, and the other a first-class stand fit to go with any kit, and which may be carried anywhere by anyone without any fear of its being laughed at, though it is home-made. I will describe the simpler one first, and the first part to be made will be the top. For this we shall want a piece of ash or any kind of tough wood about 6 in. square and  $\frac{3}{4}$  in. thick. Plane this up both sides, bringing it

FIG. 37.

to an equal thickness throughout, though what that thickness is does not matter to a trifle. Then strike a circle as large as the wood will allow, also another smaller circle (about  $2\frac{1}{2}$  in. in diameter) from the same centre, and still another one of  $\frac{5}{8}$  in. diameter. Now set the compasses to the diameter of the larger circle, and this being one-third of the circumference, will give the three centres of arms as at C C C, fig. 36. These should be so arranged that the grain of top does not run across either of the arms; it will be right if it runs in the direction of section line A B. On each side of the three points (C) now set out  $\frac{5}{16}$  of an inch, this is the thickness, or I should say the width of arm, and marks must now be drawn from these points to the outside of the smallest circle, that is the  $\frac{5}{8}$  in. one; and then the waste must be cut out by sawing outside of each of these marks as far as the middle circle, and then continuing the cut round the circle. When this is done in all three places the top will present the appearance of fig. 36, and only requires finishing off with chisel and spokeshave, and a hole

FIG. 38.

bored through the centre D, figs. 36 and 37, and holes bored through each of the three arms about half an inch from the ends E, figs. 36 and 37, and the top is finished. Now for the legs. Prepare nine pieces of wood 2 ft. 9 in. long, 1 in. by  $\frac{5}{8}$  in. Ash is a very good wood for these, but it is very heavy and rather difficult to work as well; a better kind is bass wood, or, as it is called in some places, American white wood; this is cheap and as easy to work as deal, and looks very nice as well, so this is the kind I should recommend. Now plane all these pieces up straight and square, bringing them to an even thickness and width, and then lay them all on the bench (or any flat surface), edges upwards, and square across about a quarter of an inch from one end; then  $1\frac{1}{2}$  in. from this mark square across again then take three of the pieces away, and turn the others round, taking care not to shift any of them, and mark the other end in the same way, only instead of the marks being  $1\frac{1}{2}$  in. between, they must only be half an inch. These marks are all on the edges. They must now be squared over on the sides, or one side will do, and on the marks farthest from each end. In the centre of the side in width bore a three-sixteenths of an inch hole (the marks, it must be borne in mind, are for centre of holes), with a centre bit is the best. The three pieces which were only marked at one end must also be bored at that end, and the nine pieces can then be cut off at the other marks, thus leaving six pieces with holes half an inch from one end, and  $1\frac{1}{2}$  in. from the other end, and three pieces with holes the same as the latter. The ends can be left square, or they can be rounded; the latter looks best if you like to take the trouble to do it. The three pieces with only one hole bored must now be cut off to 2 ft. 7 in. long from the centre of the hole, and the ends can now be tapered to a point or nearly so.

The stand can now be put together. First pass a bolt through one of the holes in one of the longest pieces (those  $1\frac{1}{2}$  in. from the end), then through one of the shorter pieces, and, lastly, another long piece; then screw up. Build up each leg in this way, and then place one arm of the top between the two pieces at the top end of one leg, and insert a bolt through the holes in each; put on the other two legs, and the stand is finished, and will be found very rigid; and as there is nothing about it to get out of order, it will be found very serviceable, while the cost is very little, all the fittings required being the six bolts. To pack the stand, take off the legs by taking out the top bolts, putting them in their place again, then just slack the middle

bolts and fold the bottom part of leg between the other two; the three legs will thus pack into a space of 3 in. by 2 in., and 2 ft. 9 in. long, and the top will fit in camera case, and will be found far better than the triangle commonly in use. The sizes given above are to carry a half-plate camera; for a quarter-plate a smaller top and slighter legs would do, but it is a great mistake to have a

FIG. 39.

FIG. 40.

flimsy stand, this alone, I believe, causing as many or more failures than any other one thing connected with the apparatus.

I will now pass on to stand No. 2, which will be a more complicated affair, though I must confess that, apart from looking better and packing into a smaller space, it is no better than the above, so that if you go in for use only, and do not care for appearance, you will make stand No. 1, while if you wish to be reckoned a photographic "masher" you will go in for No. 2. The remarks I made about the wood before will apply equally here, but if a handsomer stand is wanted, I should recommend black walnut, certainly mahogany could be used, but it is not suitable, not having a straight enough grain for these slight pieces. Whatever wood you choose you will require as follows:—

Three pieces 1 ft. 9 in. long,  $\frac{7}{8}$  in. by  $\frac{1}{2}$  in. for bottoms,

Six pieces 1 ft. 11 in. long,  $\frac{1}{2}$  in. by  $\frac{1}{2}$  in. for second joints.

Six pieces 1 ft. 9 in. long,  $\frac{7}{8}$  in. by  $\frac{5}{8}$  in. for top joints,

These are the finished lengths and sizes, so that they should be cut out a trifle longer, and after planing up squared off to these lengths. We also require three pieces 2 in. long, 1 in. by  $\frac{1}{2}$  in.; these must hold full thickness to allow the other pieces to slide easily. All the above being prepared, take two of the longest pieces and one of the short blocks and screw them together with the block in the middle as at fig. 41, F F being the longer pieces, and the shaded portion G the block. Now on the other end of the two pieces

FIG. 41.

thus joined, screw on the brass plates H, fig. 40, one on each side; these plates are bent, as shown in fig 43, which is a perspective sketch of one of them, and therefore they are screwed on from the bent piece into the sides of wood as shown. But before fixing these plates on one side a plug nut must be inserted (see I, fig. 40) for the milled-head screw; the proper place for this nut can be found by placing the two plates in position and marking it on the wood, and after inserting the nut the plates can be screwed on permanently. Now take one of the bottom pieces, and having pointed one end, and put on a shoe if you intend having any, then slide the other end between the brass plates H (see fig. 40, K being the bottom piece), and screw on the small guide plates L, one on each side. But I find I am anticipating again; before screwing on the plates L, mark where the screw comes, and then insert the small plate M in the bottom piece; this is to take the pressure of the screw, which would otherwise soon damage the wood. The bottom piece can now be put in and plates L screwed on, and then this joint is finished, and we will proceed to the top one. The first thing to do with this is to screw on the long brass plates N, fig. 41, across at the bottom of block, screwing both into the latter and into the side pieces, and leaving the plate an equal distance over each side, one of these plates being screwed on each side. The top pieces must be taken in hand; these must be bevelled on one side for about 2 in. from end, so that at the extreme end they only measure half an inch, and as they are  $\frac{5}{8}$  in. thick, it

will be  $\frac{1}{8}$  in. off to nothing, 2 in. higher up. This reduced end must also have a hole bored through it the same size as those in brass plates, and the ends rounded off. Striking the circle from the centre of the hole, a small brass plate, O, can also be let in on each side of reduced ends of top pieces. Now lay the latter on one side, and take the middle pieces F, and about half an inch from the end glue in a small pin on each side as shown by dotted lines at P P, fig. 41, leaving them projecting about  $\frac{1}{4}$  in., then take the top pieces again, and placing the ends between brass plates fasten them there temporarily with a screw passed through the

FIG. 42.

hole; then laying the whole flat on bench so as to keep it level, press the top piece against the pin P so as to mark them, when they can be taken out and a small hole made, so that when they are opened up the pin will enter it and it will be held firm. It is important that this hole be made at the right place, and also that it is the right size to fit the pin properly, or it will allow side play and cause the stand to be shaky. The top end of the top pieces can now be rounded (but the opposite way from the bottom end), and the plates let in which fit on the pins in the top, or the pins may be on the legs. I have shown the latter in the drawings; see fig. 42. They will both be let in the same way, so that it makes no difference which way it is, only if the pin is on the leg, a small hole must be made in the pieces F to receive it when folded. The folded pieces can now be pinned on to the brass plates N, and this leg is now finished, and of course the other two must be done in the same way, taking care that the plates, etc., are exactly the same distance apart in all three, and also that the milled-head nut which fixes the bottom sliding piece when opened, is on the same side in all, or they will look odd. You will be able to see now the reason for the bottom ends of top pieces being bevelled; it is to spread the top open, so that the ends can be pressed together to insert the pins into the holes in turntable, or triangle, or whatever kind of top you use, and they will spring apart themselves and keep firm, no stretcher being required. The method of folding is shown in fig. 39, which shows one leg complete, the dotted lines also showing one top piece in the act of being folded down, and

FIG. 43.

of course the bottom piece slides up, the whole when folded being very neat and compact. The three legs pack into a space of 3 in. by  $2\frac{3}{4}$  in., and 1 ft. 11 in. long; this is for a stand 5 ft. high when erected. For a 4 ft. 6 in. one, the length when folded would be nearly 3 in. less.

If you have a turntable in baseboard the stand is now finished, but for those who are not so fortunate I will now describe a top for the stand, so as to make it a complete article for all, and will also describe an arrangement which will dispense with the screw for fixing camera to stand, and which will allow it to be fixed or removed instantly. We will first make the top itself. This is of the shape shown in fig. 44 (not taking any notice at present of the triangular pieces); it is, as will be seen, struck out entirely by circles; and as the shape given need not be adhered to strictly, I will not take up space in giving instructions for marking it out, but content myself with simply stating that for a half-plate I should recommend the top to be six inches in diameter; and a good way to make it will be to cut out three pieces to the pattern, each  $\frac{1}{2}$  in. thick, and then screw and glue them together, crossing the grain of every one of them with the one next to it; by doing this you will be able to cut away much superfluous wood, which otherwise would have to be left for strength. A small brass plate can be screwed on at each place where the legs

come, as at U, fig. 44, the dotted lines showing the place for holes, to take the pins on legs. I think you can understand by this time how to make the top, so I will go on to the arrangement for fixing to camera. For this cut out a piece of  $\frac{3}{8}$  in. wood, a triangular piece as at S, fig. 44; the particular shape does not matter, but the long and short side T T must be parallel, and a rabbet must be made on these edges

FIG. 44.

as shown in fig. 45, which is a section; now prepare two other pieces of the same thickness and about 6 in. long, rabbetted on one edge in the same way as the others; these pieces must be screwed across the baseboard of camera, at such a distance apart that the piece S will slide easily, but without any play between them, the rabbets of course holding it there.

FIG. 45.

The triangular piece can now be fixed to the tripod top with one screw through the narrow end as at V, fig. 44; then bore a hole through both top and the other piece in the place shown by dotted lines at W, and in this hole in S insert a plug nut, so that a milled-head screw can be passed up through the hole in top into the nut, and will clamp them both together. Now to fasten the camera to stand it is only necessary to slacken the above screw a little and slide the camera on top so that the grooves in the two pieces on baseboard engage in the tongue on S; and give the screw head a turn and it is firmly fixed, and can be dis-

engaged as easily. This will be found a far more convenient plan than being obliged to turn the camera screw quite out every time the camera is taken up or down, and can be easily adapted to existing tripods.

The following is a list of fittings required for both No. 1 and No. 2 stands, and though I have left them till last, they should be obtained first, so as to be able to work them.

No. 1 STAND.		s.	d.
Six bolts with wing nuts .. ..	.. ..	2	0

No. 2 STAND.		s.	d.
Six plates, marked H in figures ..	.. ..	2	0
Six plates, marked N in figures ..	.. ..	2	0
Twelve plates, marked O in figures ..	.. ..	1	6
Six plates, marked L in figures ..	.. ..	1	0
Three plates, marked M in figures ..	.. ..	0	3
Six plates, marked X in figures ..	.. ..	1	6
Three milled-head screws and nuts ..	.. ..	1	0

#### FOR TRIPOD TOP.

Six plates, marked U .. ..	.. ..	0	6
One milled-head screw and nut ..	.. ..	0	4

My next subject will be a hand-camera.

## Harmonising Marsh Negatives.

(Continued from page 162.)

A METHOD of intensifying the shadow detail without increasing the density of the high lights to a greater extent by bleaching the surface of the negative with mercury, stopping the action before the whole thickness of the high lights is affected, washing well, and blackening with any of the usual agents, was demonstrated before us by Mr. Roland Whiting and will be found useful.

A similar method has been repeatedly advocated by Mr. Chapman Jones, the agent being the uranium intensifier. As this intensifier performs its work at one operation it is claimed that the action can be stopped as soon as the shadow detail has been sufficiently strengthened and before the lights have been intensified right through. I tried this on several occasions about a year ago, but was never successful in stopping the action at the right moment. The red colour of the intensified parts differing so much from the normal appearance of the negative makes the process a little confusing, and it is not easy to estimate the value of the added strength. At the same time I accidentally found out that ammonia would entirely remove the red deposit, and hoped that by intensifying the negative fully and afterwards painting out the red stain from the lights with ammonia I might obtain the desired results. I found, however, that it was difficult to control the action of the ammonia when dealing with fine lines, sprays of leaves, etc., and gave up the use of it. I see that Mr. J. Hodges has an article in the number of the *Quarterly* previously referred to, in which he advocates this method. He shows prints from negatives before and after treatment, to which I call your attention.

You will see from these that Mr. Hodges works his method with complete success. His acknowledged skill in all branches of photographic work entitles his method to consideration and trial by those who have time to acquire the manual dexterity necessary to work it successfully. I think the method will be found most useful when broad masses of light half-tone merging into the shadows are to be treated. It must be remembered that both Mr. Chapman Jones's and Mr. Roland Whiting's methods of intensifying the shadow detail also strengthen the high lights. Neither of these methods, nor that of Mr. Hodges, will be found satisfactory when the negative is already too dense in the high-lights. Even if we were by any of these methods able to strengthen the shadow detail to such an extent that the light half-tone would print out before the shadows were blocked up, the negative would be so dense that printing would be enormously prolonged to the deterioration of the printing paper.

What we require in such cases is that the reducer should act upon the high lights at the back of the plate, and leave the shadow detail unaltered. Should the latter be then too thin, we can intensify the whole negative without the brilliancy becoming too pronounced.

I desire to call your attention to a method of working which will yield such a result.

Shortly after giving up the use of the uranium intensifier in connection with hard negatives, I observed this formula and instructions in the Editorial columns of the *AMATEUR PHOTOGRAPHER* (October 2nd, 1891):—

"The only way to reduce the dense portions of a very hard negative without reducing the shadows is to wash free from hypo and then immerse in:

Hydrochloric acid (pure)	..	..	..	9 drops.
Bichromate of potash	..	..	..	30 gr.
Alum	..	..	..	10 "
Water	..	..	..	1 oz.

till thoroughly bleached, then wash well for an hour or more, and redevelop with a weak and well restrained ferrous-oxalate developer, and stop the development as soon as the shadows have developed and before the high lights are reduced right through, then refix."

This appeared to promise well, and I tried it. For redevelopment I used the ferrous-oxalate I had prepared for Alpha paper, as it met the requirements if weak and well restrained.

Repeated trials gave me nothing more than a ghost image after prolonged development when viewed after fixation.

On making inquiries I was told by a worker whom I considered an authority on the subject, that the chloride of silver image produced by rehalogenisation was so insensitive that a prolonged exposure to daylight would be necessary.

This necessitated previous drying to prevent irregular action and, of course, added to the trouble of the process.

I found after exposure to daylight that the image developed readily enough, but a new difficulty arose. It was impossible to tell when the action of the light had penetrated to a sufficient depth into the film, and if it went too far the hypo was unable to dissolve out the orange-coloured light product, with the result that while the shadow detail was by development of a black tone, the undeveloped high lights, if solarisation had taken place, were of a strong non-actinic orange tint, and for printing purposes just as strong as at first. The process seemed too uncertain to be of much practical use, and I abandoned it.

Some time after this, Mr. Chapman Jones referred to a similar process in which chloride of iron was the rehalogenising agent, the result, of course, being again chloride of silver.

I felt that such a process, if it could be worked with certainty, would be most useful; and it occurred to me that if bromide of silver could be substituted for chloride of silver as the haloid salt, it would be much more sensitive to artificial light, and the whole operation could be carried out in the evening. I was acquainted with, and had used, Captain Abney's formula for resensitising light-struck but undeveloped plates, viz., bichromate of potassium and bromide of potassium. This is inert upon the metallic silver image produced by development, but knowing the power of bichromate of potassium as an oxidiser to assist the acids in combining with the metals, I believed that the addition of nitric acid would accomplish my purpose. Clearly it was necessary that the bromide of potassium should be present from the first to change the nitrate of silver as it was formed into an insoluble salt, or the image would be washed away. A few trials led me to adopt the following formula and method of working:—

Bichromate of potassium	..	..	..	10 gr.
Bromide of potassium	..	..	..	5 "
Water	..	..	..	1 oz.

Bathe the plate and allow the solution to permeate the film. Pour the solution off and add to it five drops of nitric acid. Again flood the plate and the image will be converted into bromide of silver. Allow the action to proceed through the film. Bathe in three changes of alum to remove the bichromate and harden the film, and wash thoroughly in water. As the operations are carried out in white light, such as that of gas or a lamp, the plate is amply exposed by the time the washing is completed.

For development I abandoned iron as being troublesome to make up when a single negative had to be treated, and had to be followed by a clearing bath before fixation. I tried hydroquinone as being something of the same character, but found that it frilled the film off the plate, whether the caustic alkalis or the carbonates were used. The previous long soaking would account for this. I then tried pyro, and found it quite suitable. Any preservative may be used (my favourite is nitric acid), but as there is nothing on the plate but the image to be affected by

the developer, there is no necessity to use a bromide. A small trace may be useful to control development, but if any bichromate of potassium remains in the film it will unite with the bromide, and convert the image back into bromide of silver as fast as it is developed. The formula I generally use is:—

Pyro	..	..	..	..	..	2 gr.
Ammonia	..	..	..	..	..	2 min.
Bromide of potassium (if used at all)	..	..	..	..	..	1 gr.

As the shadow detail lies on the surface it will first be developed, the half-tone will follow, and the high lights will remain white when viewed from the back of the plate for some time. As the surface of the film will veil over as soon as the developer begins to act, the progress must be judged entirely from the back of the plate. The only judgment required in the process is in stopping the development at the right time. If stopped too soon, the negative will be flat; if carried too far, the negative will still be hard.

It will be well to have ready for reference a print from the negative in which the shadows have been printed to their proper depth. When the lightest half-tone which shows in the print is nearly but not quite blackened through by the developer, on viewing the plate from the back the action should be stopped, the plate washed and transferred to the hypo, which will speedily dissolve out the undeveloped silver in the high lights, leaving the negative much thinner in the high lights than it originally was. A little practice with waste negatives will give the required power of judgment.

A negative which is hard from under-exposure, and one which has been fully exposed but is hard from over-development, will not present the same appearance during redevelopment. After rehalogenisation. If the former be redeveloped right through, the high lights will appear black at the back of the plate, the high lights in the fully exposed negative will never appear black, however far the redevelopment may be pushed, and as the layer of white-coloured silver present in this case will not be dissolved out by the hypo, an allowance for this must be made in redevelopment, or the negative will still be too dense. There is no theoretical objection to the negative being again treated by the process to obtain the required reduction, but in practice there is an additional risk of stains appearing the second time. It is better to err on the side of under-development and intensify if necessary.

I found the method so successful that I should probably never have tried the chloride method again, and would have supposed it to be too uncertain for practical work. When, however, I was asked to make this process the subject of a paper, it became necessary to investigate the matter a little more closely, lest I should lead some one astray. By the experience I had acquired, I suspected the "weak and well-restrained ferrous-oxalate developer" to have been the cause of my early troubles. On rehalogenising a negative by the chloride process, I found that the exposure to lamp light was quite sufficient if developed with pyro, and the image all that was required. I would, however, in future omit the alum from the solution, and reduce the bichromate of potassium to 10 or 12 grains per ounce, and the hydrochloric acid to 5 drops. We have then two methods to work with, and though I think the bromide is a little more under control, this probably arises from my having had more experience with it.

In this process, as in all others, great cleanliness is required, and the plate must have been thoroughly freed from hypo before proceeding to rehalogenise. If hypo or other chemicals be present, thin patches and dark spots will show. If there are grease spots or finger-marks on the plate, irregular action will take place. It is best to take but one trial print from the negative, and exercise great care in doing so if rehalogenisation be thought needful. When operating on old negatives I wash them gently with dilute ammonia to get rid of, if possible, grease spots before beginning the process.

(To be continued)

**Lewisham.**—On 2nd inst., Mr. Alf. H. Miles, Vice-President, in the chair, several amendments to the rules suggested by the Committee were passed unanimously, one being that the short title of the Society be "The Lewisham Camera Club," instead of "Lewisham High Road." In the unavoidable absence of Mr. Child, his paper, "Photography for a Shilling," was read by Mr. Davidson. He gave the method of making nitrate of silver out of a shilling, and sensitising a collodion plate with it.

## Holiday Resorts and Photographic Haunts.

### COUNTY ANTRIM.

By C. E. S.

If any reader of the *AMATEUR PHOTOGRAPHER* is still in doubt as to where to spend his autumn holiday, the advice of an old amateur photographer is, "Go to County Antrim." In this short article I shall endeavour to give some directions to help the intending visitor to that lovely district; a district not surpassed in the United Kingdom for the combined charms of grand open ocean, high cliffs, barren heather-covered hills, brawling trout streams, and objects of antiquarian interest. Also, not the least important point, it is one of the few districts in Ireland where really clean and comfortable country inns are found, and those with very moderate charges.

**How to Get there.**—The quickest and best way to reach Belfast, the starting point of the tour, is by the new mail route via Stranraer and Larne. Leaving Euston at 8 p.m., one arrives at Stranraer about 6.30 the next morning, crosses the channel in exactly two hours (thirty minutes of this being in the smooth waters of Loch Ryan), and reaches Belfast at 9.10 a.m. The 3rd class and cabin return is £2 5s. 6d.

Some days might well be spent in Belfast, making short excursions in the vicinity, for no large city in the British Isles has more lovely environs. Specially worthy of visit are the Cave Hill, overlooking the city; Divis Mountain, from which a fine view of Lough Neagh is obtained; the coasts of Belfast Lough, and the valley of the River Lagan. Plates, etc., may be had at Rodman's and Neill's, both in Donegall Place, a leading thoroughfare.

The best way to see the country is to go by train to Portrush, thence by the splendid coast road to Larne, and thence by train to Belfast. A circular ticket for train and car may be had for £1, but far the best way is to walk the coast road, or if three or four persons are together, a special car may be taken for the party at an expense to each not much greater than that of the circular ticket; which expenditure is quite compensated by the fact that one can stop where one chooses to photograph. The railway journey from Belfast to Portrush occupies about two and a half hours, and gives the traveller many glimpses of charming country. It is well worth while dropping a train at Antrim to get a shot at the Round Tower, one of the most perfect specimens of these curious and interesting structures which have survived the shocks of ages. If one does not care to stop, a look at the tower, rising high over the surrounding trees, may be had from the right-hand side of the train just after leaving Antrim.

Portrush is the most fashionable summer resort in the north of Ireland, but it is still quiet and unsophisticated compared with such places as Scarborough, Brighton, or Blackpool. It boasts of one really first class hotel, the "Northern Counties," and many smaller but still comfortable and good ones. It is much better for the photographer, however, not to stay in Portrush, but to take the electric tram direct from the station to the Giant's Causeway.

The Causeway Hotel, owned by the tram company, is most excellent and moderate, and Kane's Royal Hotel close beside it is a good second-class house. Here one is in the very midst of the finest parts of the coast. The road between Portrush and the Causeway, about eight miles, runs first through the Golf Links of the Royal County Club, then along the top of fine limestone and basalt cliffs, and past Dunluce Castle, an old ruin in as fine a position, and in pre-gunpowder days as impregnable as any castle on British coasts. On this road a dozen plates may easily be used. From the hotels it is only a few minutes' walk down to the Causeway.

The pictures to be had of the Causeway itself are more interesting than beautiful, but several fine views of the cliffs may be got. Then the amateur photographer should by no means miss a walk along the Causeway Headlands to Pleaskin Head. It would be hard to name a limit to the number of views that are worth securing along this path, specially if one has a fairly good head and does not mind going pretty near the edge of the cliffs.

If the tourist has plenty of time at his disposal, he should,

while staying at the Causeway, make short day trips along the coast to White Park Bay, Carrick-a-rede Rope Bridge, and Kinbane Castle, but if time is short he may visit them on his way round the coast, returning to Belfast. All the cars stop at Carrick-a-rede, as the frail ropework structure connecting the island with the mainland by bridging over a chasm 60 ft. wide, and 90 ft. deep, is one of the "sights" of the coast. No one should attempt to cross the bridge unless they have a very good head, but if one does cross, a capital picture of the cliffs on the mainland is to be had.

Kinbane Castle is not seen if one is travelling on the public cars, for they do not stop long enough for one to visit it. Though not so grandly situated as Dunluce, it is well worth seeing, and some good views can be got from the steep bank on the north side of the little bay, showing the castle with Ballycastle Bay, and the splendid profile of Fair Head behind it.

The whole drive from Portrush to Larne by the Coast Road, about eighty miles, may be done in one day, but this is most tiring, and gives no chance of work except to a hand-camera man, and even he would lose the best bits. At least three days should be taken to see it properly. The first day, from Portrush or the Causeway to Ballycastle, includes the points of interest I have mentioned, and much pretty scenery round Ballycastle, which is a village lying near the shore at the foot of Knocklayd, a hill about 1,700 ft. high. The Marine Hotel on the shore is most comfortable and moderate.

From Ballycastle to Cushendall, about eighteen miles by the Coast Road, one may drive, but by so doing one misses the finest part of the coast. The best plan is to drive about two miles from Ballycastle, and arrange to meet your car at Torr, five miles further on, while you explore the wild promontory whose point is Fair Head, one of the boldest heads on the whole sea-line of Ireland. It is 600 ft. in height, not a sheer cliff, but formed like the ram of a modern ironclad. Beyond Fair Head is Murlough Bay, where some charming pictures may be got, as also at Torr Bay, where the road is taken again.

The "Glens of Antrim" Hotel at Cushendall is a delightful old-fashioned inn, where one revels in cream, butter, eggs, and trout in a way to dream of afterwards, when at work again in the busy town! If a day can be spared it should certainly be spent in an excursion up Glenariff, a lovely glen opening on the coast just South of Cushendall, where flashing waterfalls, quiet pools, abundant foliage, and heather-covered hills will soon make one long for a roll holder and film for a few score pictures, if not supplied with it. From Cushendall to Larne the road was generally almost at the water's edge, and many bits will catch the eye of the keen photographer as worthy of a plate. The only object of special interest passed is Garron Tower, the fine summer residence of the Londonderry family, perched on a natural terrace high up on the hill-side above the road. The views from this terrace are magnificent, and the tower itself is worth a visit.

At Larne the coast trip ends, and thence the steamer may be taken to Stranraer, or the train to Belfast, and if any amateur photographer returns home from this trip without a good stock of pictures that will afford many a pleasant hour to himself and his friends during the dark days of winter, it is certainly his own fault, and he may as well give up photography at once!

**East London Phot. Soc.**—Mr. M. A. Wilkinson, the Hon. Sec. of the above society, has removed to 28, Shacklewell Lane, Kingsland.

**Oxford Dark-Room.**—Mr. E. Claridge Druce, of 118, High Street, Oxford, has a dark-room which is free to customers for changing plates only. A charge of one shilling is made for developing.

**An Unusual and Interesting Exhibition.**—The National Chrysanthemum Society, which holds three large exhibitions of chrysanthemums during the year at the Royal Aquarium, Westminster, will, on Wednesday and Thursday next, the 7th and 8th inst., open the first of these, and great interest attaches to this early show from the fact there will be on view a number of blooms of chrysanthemums sent from Wellington, New Zealand, each bloom frozen in a block of ice, which has been brought to this country in the refrigerating chamber of one of the steamboats employed to bring over frozen meat. These flowers opened in April last, the month of the blooming of the chrysanthemum at the Antipodes. When fully matured each bloom was frozen in a block of ice, as above stated, and it is said the freshness and colours are exceedingly well preserved.

## Toning of Chloride Prints.

BY WALTER D. WELFORD.

It is quite out of my power to reply direct (spite of stamped envelopes) to all the letters I have received about the bi-carbonate of soda toning bath for gelatino-chloride prints. And at the same time I must say that I think the majority of the writers are a little hasty in their conclusions.

It is perhaps more especially unfair to complain of faulty action when using it for other papers than that manufactured by the Eastman Company, because I distinctly stated that it worked best with that brand, and to do the bath full justice that paper ought to have been used first.

The majority of the complaints (and I am of course only referring to fault finders now) made are, that it fails with the Ilford P.O.P. An unpleasant yellowish tone is the general result, it appears. I find it so myself after numerous trials, and therefore do not recommend it for that brand of paper. I can tone it without this defect, but until I am certain, prefer to further test the modification.

I fear that in saying this bath would tone several brands, as well as Eastman's "Solio," I was hardly emphatic enough in pointing out that it was *more* suitable for the latter. It certainly does tone other brands, but the results are not the same, and the tones obtained upon one or two brands would to some people perhaps be objectionable, because it must be remembered that tastes vary exceedingly in the matter of print tones.

In your last issue appear good-natured criticisms by Mr. Howson and your good self. To the former I can confidently assert that the sulpho-cyanide bath, however strong it may be, will not tone the prints to the requisite grey-black nearly so quickly as will the bi-carbonate. Moreover the tone is more of a purple or brown-black than the grey tone I obtain. To your own remark that the bath is far too vigorous and is improved by slowing its action, I can only assert that slowing the action gains nothing (except as I shall mention later on), and moreover makes the resulting tone warmer. This I have already pointed out. You are quite right in your assertion, and yet my claim for great speed and grey-black tones is not affected at all by it. Instead of 9 oz. I have used 12 and even 16 oz. of water, with the result that the action is much slower and the tone warmer. But as I was striving after a grey-black tone and rapid working, I gave the formula that best accomplished this end.

One difficulty that I had specially in view to avoid, was the appearance of uneven toning in the finished print. In some (I won't say all) of the baths that have been before us hitherto it can always be avoided by care in making the bath, and by earnest work in keeping the prints in motion. The time occupied, and the great care necessary to produce evenly-toned prints was to me a nuisance. Moreover, presuming a mark does accidentally appear, with these baths it generally remains and either further toning will not remove it, or if it does the print becomes considerably over-toned, flat, and of unpleasant colour. That is not possible with the bi-carbonate bath. A proof of this can be obtained by half-toning a print first, and then finishing it. No mark will be visible and no difference in tone. On the other hand, weakening the bath tends to make its action just the same as the others, and careful motion again becomes necessary.

As a sample of silly complaints, let me quote one: "Your bath gives dreadfully black tones, and I can't get the delicate red and brown tints I prefer." Fancy having a man like that to deal with. It is a good job that I cannot find time to write that man direct, or my letter might be of "too warm a tone."

## Photography in Geology.

THIRD Report of the Committee, consisting of Professor James Geikie (Chairman), Dr. Tempest Anderson, Dr. Valentine Ball, Mr. James E. Bedford, Professor T. G. Bonney, Professor W. Boyd Dawkins, Mr. James W. Davis, Mr. Edmund J. Garwood, Mr. William Gray, Mr. Robert Kidston, Mr. Arthur S. Reid, Mr. R. H. Tiddeman, Mr. W. W. Watts, Mr. Horace B. Woodward, and Mr. Osmund W. Jeffs (Secretary), to arrange for the collection, preservation, and systematic registration of photographs of geological interest in the United Kingdom. (Drawn up by the Secretary).

In presenting their third report your Committee desire to observe that although the number of photographs collected during the past year shows a decrease as compared with the two previous years, yet a greater proportion are of high scientific interest, and illustrate features of real geological importance. At first it was unavoidable that a considerable number of those received were only "geological" photographs in a general sense. As explained in the last report,\* it was not desired to restrict this term too greatly; but without some limit the collection would cease to represent typical geological features of the United Kingdom, and become simply a collection of landscape photographs.

The number of photographs received and registered from the date of the last report (August, 1891) to the end of June, 1892, is 112, bringing the total contents of the collection to 700. Owing to the early meeting of the Association this year, the list was closed before a complete twelve months' work could be recorded, and results have not yet reached the Committee from several of the societies which have undertaken local surveys for geological purpose. The following summary shows the geographical areas represented in the collection:—

ENGLAND :				Montgomeryshire ...	3
Berkshire	...	...	3	Northumberland ...	17
Cheshire	...	...	30	Shropshire ...	21
Cornwall	...	...	18	Somerset ...	12
Cumberland	...	...	2	Staffordshire ...	3
Derbyshire	...	...	21	Wiltshire ...	5
Devonshire	...	...	21	Worcestershire ...	2
Dorsetshire	...	...	18	Yorkshire ...	172
Durham...	...	...	16	NORTH AND SOUTH	
Hampshire	...	...	2	WALES ...	72
Hertfordshire	...	...	4	SCOTLAND ...	52
Isle of Man	...	...	22	IRELAND ...	123
Kent ...	...	...	17	MICROSCOPIC SECTIONS	
Lancashire	...	...	30		12
Leicestershire	...	...	2		
				Total	700

It will be seen from the foregoing that only about half of the English counties are represented in the collection, while the small amount of the contributions from several of those named in the list shows that considerable work is yet required to be done towards the completion of the scheme the Committee have in view.

An exhibition of geological photographs was arranged in Section C at the Cardiff meeting.

Your Committee met at Cardiff and discussed details of the work. It was decided, on the recommendation of Dr. Tempest Anderson, to adopt a standard mount of uniform size for preserving the photographs. The style of mount adopted (known as the Zaehnsdorf "self-binding" mount) is 15½ by 12 inches, and is fitted with a special guard perforated at regular intervals for binding. This is of sufficient size to hold one whole-plate, or two half-plate, or four quarter-plate views. The views when mounted may be readily arranged in any desired order, and additions or substitutions effected. A supply of mounts has been obtained, and the collection is now in process of mounting and arrangement. Forms containing descriptive details of the photographs are affixed to the mounts. It has been arranged to supply these standard mounts to donors of photographs who are willing to mount their own views; otherwise the cost of mounting will fall on the Committee. It is found necessary to have the photographs properly mounted, not only for greater convenience of reference, but also to preserve them from possible injury by handling. The value of the collection is already considerable, and will increase as it grows in numbers.

A new circular (No. 4) was issued by the Committee in November, and addressed to a large number of geologists and photographers (both professional and amateur), and also to scientific and photographic societies in all parts of the kingdom. While the Committee much appreciate the help that has been afforded from so many quarters, they would urge upon geologists generally the desirability of promptly assisting the scheme in order that their work may be proceeded with as quickly as possible. The Committee are indebted to the editors of *Nature*, the *Literary World*, *English Mechanic*, *Photographic News*, *AMATEUR PHOTOGRAPHER*, *Globe*, *Illustrated London News*, and other periodicals for giving prominence to their scheme for collecting and registering geological photographs.

The use of photographic processes for illustrating works on geology is becoming more frequent. During excursions of the

\* Report, 1891, p. 321.

Geologists' Association, several photographs have been taken by members from which "tint-blocks" have been made to illustrate papers in the "Proceedings" of the Association. In several counties active efforts are being made by local bodies for photographic surveys, and it is hoped that important geological phenomena may be made a feature of these surveys, and that copies of such photographs will be added to the collection formed by your Committee.

Reference was made in the last report to the appointment of a Committee on photographs by the Geological Society of America. The plan of this Committee is laid practically on the same basis as that of the British Association, the objects being (1) to make a photo-geological survey of America; (2) to exhibit the collection at the annual meetings of the Society; and (3) to publish a register of photographs received. The first register for 1890 contains a list of 293 photographs.

Your Committee deem it satisfactory that steps are thus being taken to carry out their own object in other countries.

Mr. C. J. Alford, F.G.S., mining engineer (of Suffolk House, Lawrence Pountney Hill, London), offered a series of geological photographs of subjects abroad, which the Committee were unable to accept owing to their operations being confined to the British islands. At the desire of Professor W. Boyd-Dawkins, F.R.S., the information is now given, as it may be of interest to many members of the Association.

It has been suggested that, in order to save trouble in printing for the purpose of supplying copies to applicants, donors of photographs should make arrangements with local photographers, to whom their negatives may be entrusted, to execute orders for prints or lantern slides. This information is added in one case in the present report, and will be continued in future lists whenever a similar arrangement has been effected.

Your Committee have kept in view the question of the disposal of the photographs and the proposed publication of a selection of approved subjects, but recommendations on both these points are still deferred until it is seen to what extent the collection is likely to reach. They respectfully request reappointment with the object of further proceeding with the work, in order that the collection may not be too partial or incomplete, but may represent as nearly as possible all important geological formations exhibited in the British Islands. Their special efforts, during next year will, it is proposed, be directed to obtaining photographs from the numerous localities not already included in the published lists. In this attempt, valuable assistance may be rendered by officers of the Geological Survey and local geologists by sending to the Secretary of the Committee early intimation of the opening of new sections showing features worthy of record by photography, in addition to particulars of old sections of typical importance, and localities of geological interest which have hitherto escaped record, or of which sketches and diagrams only have been published. It is hoped, too, that delegates of the Corresponding Societies and the officers of local Field Clubs or other bodies will bring the scheme before their members, and thus materially aid in making known the objects of the Committee.

Certain instructions have been drawn up, in order to secure uniformity of action, copies of which will be supplied on application to any member of the Committee. It is understood, however, that these are to be considered merely as a guide, and that all suitable photographs illustrating natural features of geological interest will be accepted for registration even if not complying with the whole of the recommendations stated in the circular, a copy of which is appended:—

#### *Instructions for the Collection of Geological Photographs.*

Photographs are desired illustrative of characteristic rock exposures, especially those of a typical character or temporary nature; important boulders; localities affected by denudation, or where marked physiographical changes are in operation; raised beaches; old sea-cliffs and other conspicuous instances of marine erosion; characteristic river-valleys or escarpments, and the like; glacial phenomena, such as *roches moutonnées*, moraines, drums and kames, or any natural views of geological interest. Photographs of microscopical sections and typical hand-specimens of rocks are also admissible.

I. The views should be taken under skilled geological direction, and the most typical views should be secured in preference to general views. Societies are urged to form committees for the purpose of noting sections suitable to be photographed, and arranging such work as may be possible in each district. To this end it is antici-

pated that the services of many amateur photographers may be usefully brought into requisition.

II. Size of photograph recommended:  $8\frac{1}{2}$  by  $6\frac{1}{2}$  inches ("whole-plate"); but this is *optional*. In view of the difficulty of carrying a heavy camera and plates, it is not desired to exclude smaller views when these are well-defined and clear. In the case of small negatives, when sharp, an enlargement to whole-plate size is desirable for the purpose of a place in the collection. The views should be printed by a permanent process whenever practicable. Isochromatic plates are strongly recommended to be used.

III. In order to preserve its scientific value, each photograph should be accompanied by as many of the following details as can be conveniently given. Forms for this purpose will be supplied on application.

- (a) Name and position of section or locality.
- (b) Special features shown, with illustrative diagrams, when necessary. (Further details may be given, if more convenient, on a separate tracing attached to the photograph.)
- (c) Height and length of section, and compass direction.
- (d) Name and address of photographer, or of the society under whose direction the view is taken.
- (e) Date when photographed.
- (f) Indication (where necessary) of direction of light and shade; *i.e.*, state whether taken in "direct light" or "in shade."

IV. Each photograph sent in for registration should bear a *local* number, and the accompanying form should be numbered in accordance therewith.

V. Photographs should be sent *unmounted*. Mounts of uniform size, with perforated edges for binding, to hold one whole-plate, two half-plate, or four quarter-plate views, have been prepared, and a number will be forwarded, on application, to donors of photographs who prefer to mount their own prints.

VI. Lists of photographs, copies of photographic prints and information relative thereto should be sent under cover to the Secretary to the Committee, at the *earliest possible date*, in order to facilitate the work of registration.

## Societies' Meetings.

**Aberdeenshire.**—The monthly meeting was held on the 30th ult., and was largely attended. It was arranged, consequent on a report by the Executive Committee, to hold a lantern slide competition, in connection with which two prizes would be offered for time-exposure work and one prize for instantaneous subjects, the awards to be made by a professional photographer. The prize slide will remain the property of the society, and all slides sent in will be at the service of the committee for public exhibition if required. It was also agreed that a competition in prints should be held, and it was remitted to the committee to arrange the conditions. At a later stage Dr. Mackenzie Davidson, the honorary president of the association, called attention to the forthcoming exhibition of the Home Industries Association to be opened in Aberdeen by Princess Louise, who, it is expected, will be accompanied by Princess Beatrice. He stated that he had succeeded in inducing the promoters to include in the exhibition a photographic department to represent the counties of Aberdeen, Banff, Forfar, and Kincardine, and he expressed the hope that his action in the matter would be heartily seconded by the society. He suggested that the photographic display could best be promoted through the medium of the society, and that every means should be taken to secure contributions from amateurs in the counties embraced in the exhibition. The exhibits would be the means both of bringing the society into further public notice and of securing fresh accessions to the membership. It was agreed to give the scheme the most cordial support, and a Special Committee consisting of the President (Mr. Todd Moffat), the Secretary (Mr. G. Brodie), Professor Findlay, Messrs. Barnett, Brown, Borthwick, and W. P. Robertson, was appointed to arrange details, in consultation with Dr. Mackenzie Davidson, and report to next meeting. The question of holding a special excursion on the autumn holiday was discussed, and it was agreed that those intending to take part in the excursion should consult together on the subject, and select a rendezvous.

**Great Yarmouth Camera Club.**—The members went on the 26th ult. to the Priory, Ranworth, Norfolk, at the invitation of the owner, G. Danby Palmer Kerrison, Esq. The party left Yarmouth at 9, and drove through Caister and Ormsby, a most charming part of this neighbourhood, then through Acle, which, being a flat country, does not afford such opportunities for snap-shots. Arriving at South Walsham, the party stopped to take views of the churches.

The most unusual sight of two churches, quite separate, standing in the one churchyard, and within a few yards of each other, affords an interesting subject, if not altogether a good picture. Several shots were also made in this pretty village. Resuming the journey, the party arrived at the Priory at 11.30, after a drive of about fourteen miles. The members soon got to work, and cameras were to be seen in all directions, as the charming grounds well wooded and with small rivulets running in various directions afforded ample opportunity for some pretty landscapes. At 1.30 the whole party were entertained at luncheon by Mr. Kerrison, after which a visit was made to Ranworth Hall, the residence of the Misses Kerrison. A walk through the beautiful avenue of trees brought the party to the Old Hall, which dates back to the 16th century, and connected with which there are many interesting legends, one of which is that the ghost of an ancestor of the family can be seen sometimes riding with a pack of hounds across the fields into Ranworth Broad, where they disappear. The church contains some very rich old carvings, the screens are gorgeous with figures of angels, producing a striking and brilliant effect. The day was very fine and the light good, so that the workers had everything in their favour, and some good pictures should be forthcoming from this outing, one of the most successful and enjoyable that this society has had during the season.

**Hackney.**—A meeting was held on the 30th ult., Mr. R. Beckett presiding. Minutes read and confirmed. Questions: Does the carbonate of soda reduce the printing-out paper in fixing, more than sulpho-cyanide? Reply: Slightly. How long will the sulphate of iron keep? Reply: Almost indefinitely if the bottle be full and well stoppered and acidified with sulphuric acid. When the solution is clear and green it is ferrous, and aids the image-making, but when brown, it is hydrated oxide of iron, or ferrio, and destroys the image. Discussion on the best mountant for the printing-out paper when polished was then continued. Mr. Reynolds advised gelatine, *quite* boil it, then allow to get nearly cold, though liquid; and use. If it be applied hot it will skin over. Mr. Harverson uses Aristotype Paste with good result. It was suggested that thin cartridge was as effective in keeping on the gloss as the ordinary waterproof backing. Mr. Hudson showed a magazine containing twenty-four plates—one shutter. Place in changing-bag, take out plate from one side, and put away in other. Members' work shown from Messrs. Dean, Gosling, Parfitt, Pollard, and Sodeau. A daguerreotype was shown, method of producing it explained by the Chairman. Mr. Sodeau then gave a paper on "Dark-room Illumination," explaining the theory of light and dispersion, showed the use of the spectroscope. In its absence, an efficient test is by using a piece of blue glass. If white light seen through these combined is affected by other tints, it shows the colour to be more or less faulty. Exposures of half, one, two, and five minutes were uniformly made under the same conditions, viz., light about one candle-power at one foot. Developer same, (a) Argand gas lamp, red chimney. Result: transmits red, orange, little yellow. Plate, (1) Paget's 50, one minute; image just visible. (2) Edwards's Iso. medium, half minute, visible. More fog with Iso at half minute than Paget's 50 at five minutes. (b) Red glass transmits red, orange, and just a trace of yellow. (1) Paget's 50, five minutes, no effect. (2) Edwards's Iso. medium, one minute, just visible; same as red chimney on Paget's. Altered burner to a Bray's; Paget's just showed at one minute. (c) Aurine (30 gr. to 1 oz. collodion, original burner, transmits red, orange, and fair amount of yellow. Paget's 50 just visible in half a minute; more fog than red chimney, but is counterbalanced by being more comfortable to work with, and can see with much less light than red.

**Putney.**—By the courtesy of the Director, members of this society visited the Royal Gardens at Kew on 3rd inst. Most of the members arrived at the gardens about 10.30, and proceeded to photograph in the various houses, which are only open for the purpose until 12 o'clock, when the general public are admitted. After 12 the time was spent in photographing out of doors, and as these beautiful gardens abound with objects of scientific and artistic interest, time went only too rapidly. The weather was favourable for photography, being generally fine with a good diffused light, giving plenty of time for the shadows, without destroying the high lights. While busy in the houses the weather was dull, with occasional showers of rain. This, in conjunction with the use of Isochromatic plates, no doubt accounts for the entire absence of halation from the negatives. In the houses a wide-angle lens, say of focal length less than or equal to length of plate, will be found very useful. The houses lend themselves particularly to effective stereoscopic photography, of which advantage was duly taken by one of the members. As a hint to intending visitors it may be mentioned that working with *f*/20 and Edwards' instantaneous Isochromatic plates an exposure of 20 seconds was found to be about correct in the houses, the resulting negatives being full of detail in lights and shadows, and with fine gradation. Round the lower lake plenty of good views may be found, including snap-shots

at the water fowl of various kinds. These are readily brought into position by the judicious distribution of crumbs of bread; the wise photographer will provide himself accordingly. Altogether a most pleasant and successful day was spent by the members present, regret being expressed that owing to holidays the attendance was not so large as the occasion merited.

**South Manchester.**—Ordinary meeting held on 29th ult., Mr. J. Wilkinson in the chair. After the election of auditors, several of the members, in response to the request on the circular showed exhibits of holiday work consisting of negatives, prints, etc. Mr. Reid showed several lantern-slides taken from negatives exposed with Miller's hand-camera. The Chairman brought two "Sandell" plates, one exposed for two seconds, the other for twenty seconds with *f*/16, and developed with pyro, bromide, and ammonia. In the discussion that followed, it was the opinion of the meeting that the longer exposed one was the best, although very slight difference could be perceived between the two.

**Warrington.**—The monthly meeting of this society was held on 30th ult., a very large number of members being present. In the absence of the President (Mr. T. J. Down), Mr. H. N. Houghton presided. Mr. C. Aylward, master of the Warrington School of Art, read a paper on "Composition," commencing by explaining the difficulties the amateur photographer had to contend with, well knowing how difficult it is to have full control of the composition. He went on to treat the subject from an artistic point of view, and explained the technicalities of an artist's education in taste, and briefly described the science of proportion, perspective, aerial perspective, also of light and shade. To master these laws he advocated greater attention, and reminded the amateur of his greatest fault, that of exposing a plate upon anything so long as he might be able to take something home to develop. He asked them to look further, and if they were not satisfied with the arrangement upon the ground-glass, or if it did not lead to something pleasing, not to take it, but endeavour to obtain those beautiful transient effects which nature is clothed with, perhaps only for a few seconds at a time. The lecture was illustrated by numerous sketches and a collection of photographs of Turner's works. A discussion followed. Mr. H. G. Johnstone was elected a member of the society.

#### SOCIETIES' FIXTURES.

 " 17.—**EAST LONDON.**—Excursion to Winchmore Hill.

**The Hendon (Sunderland) Industrial and Art Exhibition** was opened on 30th ult. The entries in the amateur photography section were not large, but the sets for which the prizes were awarded were excellent works of art. Photographic views of landscapes and seascapes have been kindly lent by the following:—Messrs. C. E. Cowper (Hon. Secretary of the Sunderland Photographic Association), G. T. Brown, H. Brown, John Lynn, A. Peddie, T. Dent, T. Clark, F. S. Henderson, W. Milburn, W. Broomfield, Dr. Leggatt, and the Rev. J. Bentley. There were also some complete sets of photographs which had been lent by the Editor of the *AMATEUR PHOTOGRAPHER*. The judges' awards were:—Class 103—Best set of three landscapes or seascapes: 1, Mr. G. T. Brown; 2, Mr. J. Lynn. Class 104—Best set of three instantaneous photographs: Rev. J. Bentley. Class 105—Set of six lantern slides: Dr. Legat.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns **MUST** be received by **TUESDAY MORNING'S POST**.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the *number and full title of the query* referred to.

## QUERIES.

5807. **Instantaneous Plates.**—Will any reader tell me if there is any firm that would supply me with extra rapid plates suitable for taking horses broadside on at full speed, etc.? Plates as fast as Rastman's films and Mawson and Swan's "Mawson" plate are too slow. Also, if such plates are obtainable, will they keep in India? For various reasons shall be unable to coat my own plates.—**REX.**

5808. **Developing Tent.**—Could any reader recommend me a cheap developing tent, or some other simple contrivance for developing plates for positives, as I wish to travel from one village to another, and at times by train? What I want to avoid is the dark-room on wheels, so as I could carry the required apparatus by hand.—**WET PLATE.**

5809. **Positive Appearance.**—Can any one tell me the cause of all my negatives showing the positive when looked at from the glass side, but when seen from the film side showing the ordinary negative process? I use the Ilford formula for hydroquinone and eikonogen; and for fixing, 4 oz. hypo to 10 oz. water. I think it must affect the printing qualities of negative, as prints have a muddy appearance.—**POSITIVE.**

5810. **Copying.**—Can any one inform me of the best way of making a negative from old c. de v. print to cabinet size?—**ONE IN A FIX.**

5811. **Elizabeth's Oak.**—Will someone kindly tell me the name and address of a dealer who could supply me with a photograph of Queen Elizabeth's Oak in Hatfield Park?—**H. I. C.**

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## QUERIES UNANSWERED.

July 15th.—No. 5756.

" 22nd.—Nos. 5763, 5768.

" 29th.—Nos. 5777, 5778.

Aug. 5th.—Nos. 5779, 5780, 5781, 5785, 5786.

" 19th.—Nos. 5790, 5791.

" 26th.—Nos. 5794, 5796, 5797, 5798, 5799.

Sept. 2nd.—Nos. 5800, 5801, 5802, 5803, 5804, 5805, 5806.

## ANSWERS.

5795. **Copying.**—Why did you put tissue paper over the print? It is not surprising that it was a failure. Try again without the tissue paper, incline the print so as to get no light reflected from its surface, give rather a short exposure, and develop slowly, so as to get as much contrast and also as much detail as possible.—**R. A. R. BENNETT.**

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us before **TUESDAY MORNING'S POST** if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—**ED. AM. PHOT.**

**E. W. MALE.**—The pink tone may be caused by lack of gold or by toning in too strong a light. You give no information as to method of working.

**A. K. TRAYLER.**—Letter by post.

**HERBERT A. SALWAY.**—The developer which has succeeded best in our hands is Chapman's.

Hydrokinone .. .. .	40 gr.
Eikonogen .. .. .	120 "
Sodium sulphite .. .. .	480 "
Citric acid .. .. .	20 "
Distilled water to .. .. .	20 oz.

Potassium bromide .. .. .	5 gr.
Sodium carbonate (crystal) .. .. .	60 "
hydrate .. .. .	30 "
Distilled water to .. .. .	20 oz.

For use mix in equal parts.

**H. F.**—(1) Not necessarily absolute sunshine, but a good light. (2) Mawson, Barnet, and extra rapid Edwards's isochromatic, Imperial, Paget, and any one you choose. (3) The acid fixing bath cannot be used for prints. (4) The pink tinge is not prejudicial to the toning bath.

**WATCH.**—Your nearest club, we should say, would be the Tooting Camera Club, Hon. Sec., G. H. Dollery, "Glicion," Lucien Road, Tooting. There is a Lewis-ham, Sydenham, S. London, Loughborough, Brixton, and Clapham, all not far off. (2) The negatives given by the camera named are so small as to be useless. As an example of ivy the print is by no means bad, but your camera was not straight, and it is rather over-printed.

**D. J. GADSBY.**—You do not state whether you allowed the bath to stand before using, or whether the prints were washed first or not. We should say that the yellow tinge is due to sulphur toning. Either let your bath stand at least six-four hours before adding the gold, or else heat gently for half an hour, then filter and add the gold, and well wash your prints first.

**G. T. R.**—There is no easy way of obtaining a good print from the fogged negative; it might be possible with a good deal of care to so construct a vignetter as to allow the fogged part to print more than the edges.

**ONE IN A FIX.**—Any whole-plate by Taylor, Crouch, Wray, Beck, or "Optimus" would suit your purpose.

**DUDLEY.**—You want one of the special cameras made for stamp portraiture. Write to Fallowfield, 146, Charing Cross Road, and ask for quotations.

**J. P. and W. W.**—(1) Bartolozzi tones are extremely difficult to obtain on gelatin-chloride paper. The best method is to tone very slightly with acetate and gold bath, and then fix. Practically you cannot obtain these red tones, though you can get near them. (2) For bromide prints bleach the fixed and well-washed prints in

Sulphate of copper .. .. .	1 part
Distilled water .. .. .	100 parts

Potassium bromide .. .. .	1 part
Distilled water .. .. .	100 parts

Mix these two solutions; when the print is thoroughly bleached, wash well, and develop after having exposed to daylight for some ten minutes, or develop in daylight with the following developer:—

Sodium sulphite .. .. .	20 parts
Eikonogen .. .. .	4 "
Water .. .. .	300 "

Carbonate of potash .. .. .	50 parts
Distilled water .. .. .	300 "

Solution A .. .. .	5 parts
Solution B .. .. .	2 parts
Water .. .. .	200 "

Sodium sulphite .. .. .	4 oz.
Tartaric acid .. .. .	20 gr.
Water .. .. .	16 oz.

Nitrate of lead .. .. .	4 parts
Ferricyanide of potash .. .. .	6 "

Yellow resin .. .. .	24 "
Benzine or ether .. .. .	2 oz.

and rub the glass with this, you will have no difficulty in stripping the chloride prints. (4) The lead bath will not give permanent prints. Avoid this. Referring back to Bartolozzi prints, you will find that Alpha paper and carbon printing are the best for these tones. In the latter a special Bartolozzi tissue is sold, which gives very fine results. The carbon process is neither expensive nor difficult; why not try it?

**AN AMATEUR.**—For copying oil paintings and coloured objects generally you must use isochromatic or colour-sensitive plates. There are two brands made in England, one by Edwards and Co, The Grove, Hackney, and the other by the Ilford Co. Use medium isochromatic, and if there is any quantity of blue in the picture, you must use a yellow screen, placed before, between, or behind the lenses; in fact, all pictures should be copied through a yellow screen. The exposure will depend so much upon the tone and character of the picture and pigments that we cannot give you much help—but if a very dark picture it may require about three or four hours' exposure with a yellow screen and a small stop. Very recently painted, bright pictures, on the other hand, will require probably about half an hour under the same conditions.

Our leaders on colour will shortly become "colour and photography," and give you a good idea on the subject. Pyro and ammonia is the best developer. Write again if you like.

**R. A. MICHIE.**—See "Our Views" on Noah's Ark.

**DOZEY G.**—Date not yet fixed for criticising prints. Two ounces of hypo would be sufficient to fix a sheet of paper.

**H. J. C.**—Probably your negatives want reducing; if so, the acid fixing acts too slowly. Try Howard Farmer's hypo and ferridcyanide. (2) If carefully applied, the negative preserver is as effectual as any other varnish.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence.

Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the **AMATEUR PHOTOGRAPHER**, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques of Postal Orders, made payable to **Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.**

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 5d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the **EDITOR, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C.**, who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent. upon the sale price of the apparatus.

**Bicycles, Tricycles, etc.**—Exchange Safety bicycle, ball bearings complete with lamp, bell, brake, etc., in excellent condition. Wanted, hand-camera, good make, or offers?—**P. G. H., 23, Bonfield Road, Lewisham.**

**Cameras, etc.**—Half plate camera (Fallowfield), all movements, Eastman rollholder, and three slides, 5 guineas; approval; deposit.—**Broomhall, St. Margaret's, Twickenham.**

**Cameras, Lenses, etc.**—London-made high-class half-plate double extension camera, best leather bellows, reversing back, every necessary movement, one double slide, 47s. 6d.; very finest half-plate extra-rapid rectilinear lens, exquisite definition, Waterhouse diaphragms, 22s. 6d.; great bargains; approval.—**Cyclist, 8, Kenilworth Road, Willesden Lane, London, N.W.**

New whole-plate long-extension mahogany leather bellows camera, Underwood's, folding tail-board, reversing back, one slide, look up case, wide-angle and extra-long focus lenses, by Laverne and Taylor, cost over 10 guineas, cash 6 guineas.—**A. Carre, 39, Hauteville, Guernsey.**

Griffith's hand-camera with finder, good condition, 16s.; half-plate camera and lens, 26s.; quarter instantaneous shutter, 3s. 6d.—**Nutt, 242, Fitzwilliam Street, Sheffield.**

For sale, high-class half-plate photographic apparatus, camera by Watson, lens by Dallmeyer and Ross, Thornton-Pickard and Newman shutters. For particulars and price apply, **H. Lewis, 35, Broad Street, Reading.**

**Exposure Meter.**—Watkins' exposure meter, nearly new, 9s.—**Cooper, The Lodge, New Road, Bocking, Essex.**

**Hand-Cameras, etc.**—5 by 4 Kodak, equal to new, 30 films, fitted to hold 100, a bargain, £6 5s.—**264, Hainton Street.**

Kodak No. 1, perfect, containing film, also two unopened packets film, 100 each, 45s.; Kodak No. 4 Regular, perfect, containing film, 7 guineas.—**Pierrepont, Thames Ditton, Surrey.**

Hand-camera, B daylight Kodak, has double lens, revolving stops, view finder, shutter for time or instantaneous exposures, and patent locking and registering device, to carry spool of films for 24 exposures, covered in black leather, new last July, take 55s.—**O. Banks, 19, Maurice Street, Nelson, Lancs.**

Hand-camera (Houghton's Automatic), carries 12 quarter-plates, Thornton-Pickard shutter, automatic changer, rapid rectilinear lens, compact instrument, 9½ by 5½ by 4½, has done good work, price £4 10s.—

J. B. Hartness, Lauriston House, Ceylon Place, East-bourne.

No. 1 Kodak with about 25 to 30 films, as new, cost £5 5s., take £2 10s.—Simpkins, Ivy House, Basing-stoke.

**Lenses, etc.**—7 by 5 Optimus Euryscope, cost £4 7s. 6d., sell £3 3s.; 8½ by 6½ Burr's rapid rectilinear, cost £3 10s., sell £2 5s.; Waterhouse stops, condition as new.—Adams and Son, 57, Haymarket, S.W.

Half-plate R.R. lens, cost 75s., price 35s.; Optimus whole-plate tripod, 10s. 6d., good condition.—B. B., Colville Library, Talbot Road, London, W.

Hockin's half-plate Desideratum rectilinear wide-angle lens, new and perfect, lowest 25s.; trial allowed on receipt of cash.—Griffin, Chemist, Chingford, Essex.

Ross' landscape lens, 12 by 10, 2 guineas.—Murrice, 16, Lee Crescent, Portobello.

For sale, Lancaster's quarter-plate combination rectigraph lens, price £1.—Heath, West View, Kendal.

**Sets.**—Underwood's 1892 half-plate Instanto set, good as new, only 68s.—Ricketts, Cheltenham House, Stroud.

Quarter-plate set, complete, all accessories, cost recently £3, sacrifice 27s. 6d.—85, Dalberg Road, Brixton.

Whole-plate long-extension Rayment's patent camera, good as new, reversing frame, and all motions, three double dark slides, twill lined focussing cloth, all in strong waterproof canvas case, three-fold tripod, 5 guineas, cost £10; whole-plate wide-angle rectilinear lens, with rotating diaphragm, Black Band series, £3; Optimus book detective camera, fitted Optimus lens, three double dark slides, complete in leather case, lined velvet, with lock, never used, 3 guineas, cost 6; good whole-plate changing bag 4s.; Decondun's photometer, 5s.; Harter and Driffield's actinometer, brand new, 6s.—Miss Hardman, Elmshale, Reigate.

Full-plate Lancaster camera (Merveilleux), with stand, three double dark slides (two with carriers), new instantaneous shutter, four printing frames, three developing dishes, one dozen Ilford full plates, waterproof cases for camera and stand, original cost over £8, will take £4 5s.; camera, etc., may be seen at office of this paper.—No. 330, office of this paper, 1, Creed Lane, E.C.

Will exchange my half-plate Lancaster's Le Merveilleux camera, double back, handsome tripod, and rapid rectilinear lens, for good quarter-plate camera with extra backs, tripod, and rapid rectilinear lens by good maker.—No. 331, office of this paper, 1, Creed Lane, E.C.

Half Instantograph, six slides, Newton lens, Thornton shutter, £4.—E. Ellis, High Street, Wavertree, Liverpool.

Quarter Underwood's 1890 Instanto, every movement, six double backs, R.R. lens, bag, tripod, shutter, £2 2s.—Bartlett, 3, Ainslie's Belvedere, Bath.

Underwood's Instanto half-plate camera, Ashford stand, five double slides, R.R. and W.A. lens, and complete apparatus for turning out photographs, £8; worth double.—Davies, 22, Market Square, Pontypridd.

Underwood's half-plate President (1892) camera, two slides, Taylor and Hobson's rapid rectilinear, iris diaphragm, Thornton shutter, Ashford tripod, £7.—66, Middle Street, Yeovil.

**Sundries.**—Nearly new, £4 gent's small silver English lever hunting watch offered in exchange for a half-plate camera, tripod, and two or three double backs; approval; deposit.—No. 332, office of this paper, 1, Creed Lane, E.C.

Whole-plate Lancaster's Multum-in-Parvo enlarging camera, quarter-plate double dark slide for International camera, quarter Hiero washer, quarter Eclipse changing bag, stiff American cloth case to hold quarter set. What offers?—Apply, Thirkell, 313, Southwark Park Road, S.E.

## WANTED.

**Cameras, etc.**—Wanted, good half-plate camera or outfit, Chadwick's preferred, maker's name, full particulars, lowest cash price.—Wyndcliffe, Ilkley.

At once, cheap half-plate camera, slide, and stand, no lens, good maker.—Brown, Toll Buildings, Coat-dyke, Coatbridge.

**Hand-camera, etc.**—Omnigraph wanted. Particulars and price to Crosbie, 21, Gloucester Crescent, Hyde Park.

**Lenses, etc.**—Wanted, whole-plate Lancaster's Instantograph lens and shutter.—Jackson, 71, Oxford Street, Manchester.

**Rollholder.**—Eastman's 6½ by 4½, second-hand.—16, Gladstone Place, Edinburgh.

**Sundries.**—Wanted, AMATEUR PHOTOGRAPHER posted regularly weekly. State lowest price to Cope-man, Henstridge.

*It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.*

**Bargains in Hand Cameras.**—Fallowfield's Facile, fitted rapid rectilinear lens, carries twelve quarter-plates, as new, £3 17s. 6d. Optimus magazine hand-camera, covered leather, carries 12 quarter-plates, finest Optimus rapid rectilinear lens, two finders, shutter, etc., as new, take £5 5s.; Talmer hand-camera, carries 12 plates, fine lens, two large finders, time and instantaneous shutters, as new, take 65s.; Swinden and Earp hand-cameras, carries 20 quarter-plates, fitted Taylor and Hobson's best rapid rectilinear lens, roller-blind shutters and case, as new, £6 15s.; Steinheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Lancaster's Omnigraph, covered leather, good lens and shutter, take 15s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, take 27s. 6d.; Griffiths' best quality hand-camera, carries six ¼-plates, two sunk finders, good lens, pneumatic shutter, take 30s., cost 42s.; quite new, all above are warranted as described. On view, City Sale and Exchange Rooms, 54, Lime Street, corner of Leadenhall Street, City (late Goy's Medium). Second hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus of every description bought, sold, or taken in exchange. Inspection invited.

**Bargains in Lenses.**—15 by 12 rapid rectigraph lens, Silver Ring, iris stops, grand definition, take £5 17s. 6d., quite new; whole-plate portrait lens, rack focussing, Waterhouse stops, works f/6, £2 17s. 6d.; whole-plate Voightlander's rapid rectilinear, fine definition, best order, 30s.; whole-plate Optimus rapid landscape lens, quite new, rotating stops, 35s.; whole-plate Lancaster wide-angle lens, rotating stops, 15s.; 8½ by 6½ Ross rapid symmetrical, Waterhouse stops, grand definition, as new, £4 10s.; Wray's 7½ by 5 wide-angle rectilinear, rotating stops, as new, 47s. 6d.; half-plate aluminium rapid rectilinear, by Parkes, Waterhouse stops, 30s.; half-plate Ross' portable sym-

metrical, rotating stops, 4 in. focus, finest order, 45s.; half-plate wide-angle, by Morley and Cooper, rotating stops, as new, 27s. 6d.; half-plate Ross' rapid symmetrical lens, as new, moveable hood, Waterhouse stops, take £3 17s. 6d.; Wray's landscape, Casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, take 70s.; Ross' c. d. v. portrait lens, rack and pinion, finest condition, 35s.; Shew's c. d. v. portrait lens, Waterhouse stops, rack and pinion, as new, take 21s.; Optimus 5 by 4 rapid Euryscope lens, by Perken, Son, and Rayment, Waterhouse stops, as new, 47s. 6d.; quarter-plate Optimus rapid rectilinear, by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

**Bargains in Cameras and Sets.**—12 by 10 camera, double extension leather bellows, wide-angle movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide, changing box, for 24 plates, also changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; 7½ by 5 long-focus camera, by Gotz, wide-angle movement, leather bellows, reversing back, rapid rectilinear lens, and folding stand, set complete, £5 15s.; half-plate Underwood's Instanto, wide-angle movement, double extension, fitted rapid rectilinear lens, slide, and folding stand, £3 17s. 6d.; half-plate camera, by Houghton, all latest movements, grand article, fitted three double slides, rapid rectilinear lens, and double folding stand, £6 10s.; half-plate 1892 Instantograph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, three-fold stand and case, take £6 10s.; quarter-plate Lancaster's Merveilleux set complete, 15s.; Lancaster's Convention set complete, camera, lens, shutter, slide, and stand, as new, 40s.; quarter-plate aluminium Instantograph set complete, quite new, camera, lens, slide, shutter, and stand, 50s.; quarter-plate Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

**MISS F. E. CROSS, Artist and Retoucher.** Negative Retouched free, as specimen. Price list on application.—2, Raul Road, Hanover Park, S.E.

**A**NY kind of high-class Glass Writing and Gilding done in exchange for photographic apparatus of good quality.—No. 329, office of this paper, 1, Creed Lane, E.C.

**RICHARDS' Patent Corners,** for mounting photos, R prints, scraps, etc., in albums, scrap books, and mounts; clean, convenient, ornamental, self-contained and always handy. Ready gummed, price 1s. the box or by post 1s. 1½d.—F. Watson, 17, Dartmouth Street, Westminster, S.W.

**SOCIETIES' MEETINGS.**—Ashton—Burslem—Crewe—Croydon—Derby—Devonport—E. London—Hackney—Lewes—London and Provincial—N. London—N. Middlesex—Richmond—Rotherham—Sheffield—S. London—Wigan—Woolwich Polytechnic.

**EDITORIAL DEPARTMENT.**—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

**TERMS OF SUBSCRIPTION.**

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	6s. 6d .....	13s. 0d.
OUT OF POSTAL UNION ..	7s. 9d.....	15s. 8d.

**TRADE ADVERTISEMENTS** are received up to Tuesday morning.

**PUBLISHING DEPARTMENT.**—All letters containing Subscriptions, Orders, Remittances, SALE and EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZEL, WATSON, and VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE and EXCHANGE Advertisements (at the charge of Three Words for One Penny) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

"Amateur Photographer" Monthly Competition, No. 40.—"PORTRAITURE AND FIGURE STUDY." Latest day, Sept. 19th.—Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, October 14th.)

THE AMATEUR PHOTOGRAPHER Annual Lantern Slide Competition closes on the 30th inst. We warn our readers not to be late, as the judging will take place as soon after the 30th inst. as possible. The slides will be shown at the P.S.G.B. Exhibition on Saturday, October 8th.

We commence this week a column of "Chit Chat," by a well-known "Chatterbox," who, however, declines to sign his name in full. Anonymous writers too often make use of their position to run amuck against one and all, and not always in a kindly spirit. Our "Chatterbox," however, is very good-tempered, and though he may have a quiet dig at some of our contributors, as he has sometimes privately done to the Editor, we think we may say from personal experience that he never draws ill blood. Besides, he has always the fear of the editorial blue pencil with its deleting powers.

OUR contemporary, the *Chemist and Druggist*, in reviewing the "Amateur Photographer's Annual" this year, remarked, "Amateur photographers are surely the pet children of journalism."

Well, Jonathan Fallowfield and the Britannia Works add their quota to the spoiling of the photographer by issuing gratis monthly leaflets; and now Elliott and Son, the makers of the well-known "Barnet" plate, are issuing a four-page paper called *The Photographer* (by the bye, we thought this title was already in existence), which is for gratis distribution through dealers to amateurs. One good feature about this last comer is that "puff" is to be absent, and if, as promised, illustrations are included, the demand will be great. Next month there is to be a carbon print.

THERE is an old saying that things which are obtained for nothing are never valued. There may be some truth in this, but our Monthly Illustrated Supplement, we think, pleases many, and is valued by them. This week, we think, we have broken the record, as we have no less than eleven illustrations. We hope our readers will appreciate our efforts to keep well to the front.

PHOTOGRAPHY has been for some time used by several of the great railways as a means of ornamenting the interiors of their carriages, and we believe the G.W.R. were the first thus to call in the aid of our art. An extension of the idea may now be seen at Paddington, where a large

screen has been erected, close to the entrance to the subway, containing a large number of platinotypes, some of very fine quality, of the principal places to be reached by this line. When we were there last week, there was quite a small crowd looking at them.

A FEW minutes mixing with the crowd allowed us to overhear some curious remarks. One gentleman suggested they were engravings; another, evidently in the know, said; "Oh! no, they're platinotypes," when back came the answer, "What, tintypes! I didn't know they did them so well as that now." We did not hear the explanation that probably followed, as we caught the parthian shot of a cynical critic, "Ah, they can't get them in colours yet."

This remark sent us off, sadly thinking that it is no light matter to try and teach the British Public science. Even some of our daily papers, we note, have given it up in despair, though really we should have thought that after the late series of letters on Lippmann's and Ives's work, more would have been known on this subject.

H. W. VOGEL, who has been writing several letters to our papers on Ives and his work, has, we hear, formed in Berlin, in conjunction with one Ulrich, a company, to reproduce some of the leading pictures in their gallery by means of chromo-collotype, and new and far superior results are claimed for the new workers.

MANY of our readers will remember that as far back as 1890, in the *Photographic Quarterly*, we gave a specimen of chromo-collotype done by Messrs. Waterlow and Sons, an English firm; and since then we have had given to us samples of every advance they have made. The conditions for perfect work in chromo-collotype are so difficult, that reluctantly everybody has come to the conclusion that it is not a commercial process.

On the other hand, printing in colours with half tone or "tint" blocks has yielded some very good results, and the latest examples shown us this week, not pulled on paper but on satin, are very fine. We hope to be able to shortly give our readers a specimen of this colour printing.

ALTHOUGH little more than a twelvemonth old, the Leytonstone Camera Club is a vigorous prodigy, and is anxious to show itself off, and for that purpose will hold an exhibition, which will be open to amateurs only, at the Masonic Hall, Leytonstone, on November 10th, 11th, and 12th. The Committee offer eight silver and eight bronze medals in the following classes, and under the following conditions:—

#### CLASSES.

*Members only.*—(A) Landscape, seascape, and architecture. (B) Portraits and figure study. (C) Enlargements. (D) Lantern slides (set of six).

*Open.*—(E) Landscape, seascape, and architecture. (F) Portraits and figure study. (G) Enlargements. (H) Lantern slides (set of six).

#### CONDITIONS.

(1) Every exhibit shall bear the exhibitor's name and address on the back, also price, if for sale. (2) Every exhibit must be properly described on the official entry form and sent with entrance fee, which must be received by the Hon. Secretary not later than October 25th. Exhibits must be delivered, carriage paid, not later than October 31st. (3) All exhibits to be framed if possible; no unmounted prints will be allowed to compete. (4) The whole of the work, exposure, development, retouching, printing, and toning, must be the entire production of the exhibitor. (5) Any exhibit sold during the exhibition shall be subject to a commission to the Club of 10 per cent. (6) Exhibits having been awarded a prize previously will not be eligible for competition. (7) No competitor will be allowed to take two prizes of the same value; if awarded it will pass on to the next highest. (8) All exhibits not removed at the close of the exhibition will be returned to owners. Carriage forward at owner's risk. (9) Exhibits must bear no title or description whatever on the front, as they will be numbered and described in the official catalogue. (10) In Classes A, B, E, and F only direct prints are

eligible. (11) The successful slides will be passed through the lantern each evening.

Mr. A. E. Bailey, of Rose Bank, South West Road, Leytonstone, will be pleased to give any further information.

MOST of our readers are aware of the existence of a particular school in photographic circles which claims that photography is rather more than a science, in fact, that it is an art. Probably also they are aware that several of the leading workers consider that at the P. S. G. B. exhibition the art has far less than justice done to it; so this school intend to hold an exhibition of their own. Whilst considerable rancour and ill-feeling has been introduced into the discussion Mr. A. Horsley Hinton has in this issue calmly and dispassionately placed before our readers what may be accepted to be the reasons why the claims are advanced. We need not, of course, point out that our columns are open to reply, should any one feel disposed to do so.

THIS is notoriously the age of cheapness, and whilst there are many amateurs who consider that the present prices charged for lenses are by no means exorbitant, there are others who, looking upon the lens as a bit of common glass in a bit of brass tube, consider the prices excessively high. To these the intelligence will be welcome that an optician of Baltimore, U.S.A., has perfected an ingenious arrangement, by means of which 400 lenses can be cut, ground, and polished at once. It is said to consist of a saw and a number of metal discs, both flat and oval, in which the glass is secured by clamps, and which are kept in constant motion by means of a pulley and wheel operated by a motor. Unfortunately, no information is given as to how long it takes to complete the lenses; all we want now is another ingenious arrangement which shall calculate the curvature of the surfaces and mount the lenses, and we shall be able to purchase first-class lenses at the same price as Oxford eye-glasses or spectacle lenses.

MR. HERMANN KRONE contributes to the current number of *Wiedemann's Annalen* some experiments with Lippmann's colour photography. He says that the correct rendering of the various colours depends upon a high degree of accuracy in the proportions of the finely divided silver haloid and the colour sensitiser, as also upon the temperature of drying, the exposure, and the development. If the essential conditions are not fulfilled, it may happen that yellows appear in the place of red, or that green exhibits a direct transition into violet, the blue being unrepresented. The result also depends upon the amount of water contained in the film, as influencing its thickness, and in the case of the solar spectrum upon the altitude of the sun. With a very long exposure the infra-red appears as a dark purple, and the ultra-violet as a yellowish-pink lavender colour. Mr. Krone has also succeeded in producing coloured photographs without Lippmann's mercury mirror. He simply covers the film with black velvet, exposing as Lippmann did, through the glass. In this case the reflection from the inner surfaces of the glass takes the place of that from the mercury. The exposure has to be considerably prolonged, and the colours towards the red end are less pure; but the blue, violet, and ultra-violet are quite as brilliant and well defined as in the mercury process.

PHOTOGRAPHY is often used in the household for decorative purposes, and for amusement in the shape of lantern slides and albums of views. But whilst these appeal to the older children, the following very easily made toy, suggested in a

contemporary, will please many of the younger children :—

"Take two negatives of the same person, but in two different positions; for example, a woman taking water at a pump. In the first picture the arm will be raised, then lowered in the second, and the two attitudes of the woman will be in relation with the two positions of the arm of the pump. Of these two negatives print two proofs, and place the two images (toned, fixed, etc.) on the two opposite surfaces of the same cardboard, the two images being reversed with reference to each other in the same manner as the medallions on a coin. Tie a string on each side of the cardboard; by twisting it between the fingers you will cause the cardboard to revolve rapidly, and you will obtain the sensation of the motion of a person pumping water."

WE recorded last week the arrest of a photographic spy in Brisbane, and now the report appears that two Americans were found photographing forts on Canadian ground. The apparatus and plates were confiscated, and the Americans incontinently bundled back into the States.

DURING the old wet-plate days when quantities of collodion formed part of the stock-in-trade of every professional photographer, the fire insurance offices charged a very heavy premium in consequence of the increased risk. But since the introduction of dry plates these risks have been so reduced that one rarely hears of any accident from the use of collodion, which is now, except for photo-mechanical and lantern-slide work, only used for enamelling prints. An accident at a photographic enameller's in Paris, has unfortunately been the cause of four deaths, and such serious injury to two other persons as to render hope of life almost impossible. The enameller, with the assistance of his wife, was arranging his bottles when, according to the reports, the wife upset a sixteen-quart jar of collodion, and the liquid running over the floor, the vapour was ignited at a fire in an adjoining room, with the above disastrous results.

ONE naturally wonders what an enameller was doing with a four gallon bottle of collodion, and possibly the more true report is that one small bottle only was upset, and that other bottles exploded with the heat and concussion. Although ether is a very light liquid, having a specific gravity of about .720, its vapour is very heavy, being two and a half times heavier than the air, and it is a well-known fact that when a bottle of ether or collodion is tilted on its side, the vapour may be seen to pour out like a stream of the liquid itself, and if the hand be held below, the cold produced is easily noticeable.

THE above lamentable occurrence gives the opportunity to a daily paper, well known for its quasi-scientific writing, to treat its readers to a homily upon how much emulsion the sixteen quarts of collodion would make, thus unfortunately showing their ignorance of the process of enamelling.

IT may be of interest and service to our readers of an inventive term of mind if we record the fact that two French gentlemen have just patented a hypodermic syringe all over the world. It seems that an article can be protected in sixty-four countries. Sixteen of these are in Europe, eight in Africa, four in Asia, twenty-seven in America, and nine in Oceania. The total cost of the patent in all these countries amounts to only £3,600.

THE committee of the Hove Photographic Exhibition, to be held on the 21st and 22nd inst., have extended the time for sending in exhibits. Lantern slides can be received up to Monday, 19th inst., and prints to the evening of the 20th. Lantern slides and prints may be sent in to Mr. J. Williamson, 144, Church Road, Hove, from whom all particulars may be obtained. We published the text of the classes and conditions in our issue of July 29th, p. 62.

## Chit-Chat.

MISS CATHERINE WEED BARNES, in a paper read before the Birmingham Photographic Society, gives English amateur photographers a good idea of the present position of amateur photography in America. Miss Barnes touched upon several matters which might well receive attention on this side of the "herring pond." In making a comparison between English and American apparatus, she pointed out some of the advantages possessed by the light American plate holders over the beautifully made but bulky and heavy English double backs, and having, during the last few years, had more than one camera in constant use fitted with light plate holders, I feel bound to admit that there is a great deal of truth in the lady's remarks. There is still room for improvement in dark-slides and particularly in special holders for films. Many amateurs who now use plates would use films if a light and reliable holder could be obtained for them. It should take the form of a solid back, and be capable of holding two films; it should be about half the weight and thickness of an ordinary dark-slide, and the shutters should draw completely out, and close with a properly constructed valve, and finally the film should be held down on all four sides. Such a slide can be obtained in America, but would it not be worth some English manufacturer's while to place a similar slide upon the English market?

LANTERN-SLIDE making and lantern slide exhibitions, as Miss Barnes reminds us, have become very popular in America, and the plan which obtains there of having slide-testing nights is one very much to be commended, and which might with advantage be adopted by some of our English societies. As many amateurs are now busily engaged in making slides for the winter, the opportunity is afforded me of having a good growl at the very inferior quality of many of the slides exhibited at society lantern shows. The committees who are responsible for the success of these entertainments should, in mercy to the producers of the bad slides, and to the audiences, have the discretionary power vested in them of rejecting slides which are not up to a certain standard of merit. Unfortunately for lantern slide-making as an art, the general public is not yet capable of discriminating between good and bad work, for frightful specimens of the "soot and whitewash" order frequently come in for the largest share of applause.

A great many amateurs have now returned from their holidays and are busy developing their negatives, and getting ready for the exhibitions. Many, of course, cannot choose their own time for the annual holiday, but the man who can defer it until late in September or October will have many advantages over his brethren of the tripod whom circumstances have compelled to take their holidays earlier. True it is that the working day is woefully shortened, but the advantages obtained in the direction of better atmospheric conditions more than compensate for the loss of actual daylight. Particularly is this the case in mountainous or hilly districts, when the presence of a slight haze, or mist, is indispensable in order to secure relief, and to avoid the unhappy flatness which is so characteristic of photographs taken in bright weather during the summer.

WILL the P. S. G. B. Exhibition be a failure or a success? is a question exciting much speculative opinion at the present time. I hear that pictures are coming in well, and from able men, though exponents of the "smudgy" school may not be very numerous represented. However, they

are, if report speaks truthfully, to have a "show" all to themselves by and bye, whereat, we are told, we shall see great things.

I AM not "down" on hand-cameras by any manner of means, and I greatly respect the man who can use one intelligently, but to see the user of one give a snap exposure on a dull day to a dark glen view, and exclaiming at the same time, "I have got it," was an experience which sent me home musing, a sadder and a wiser man, but wishing, oh! so ardently, than I was "one of those plate-making fellows," for surely, if nothing else, it is good for trade.

I AM stopping—but, no, the Editor does not wish me to disclose my identity, and wishes me, I think, to be mistaken for the "other fellow"—well, at a place where I have spent many a delightful holiday before. Four years ago I photographed my host's house, and sent him a print on gelatino-chloride paper, which, framed and glazed, has ever since hung on a wall which in winter is the reverse of dry, and during the summer is exposed for the greater part of the day to the direct rays of the sun. Notwithstanding these somewhat adverse conditions, the print is as bright and fresh as on the day when it first left the toning bath, which, by the way, Mr. Editor, was the combined fixing and toning bath, which you are, perhaps, not unjustly, so down upon. Now, my dear readers, please do not imagine that I am narrating this with the idea of impressing you with the belief that the unknown quantity addressing you is a most careful worker, for the probability is that that print was washed in a rather perfunctory and hasty manner. But the question of the permanency, or otherwise, of prints upon gelatino-chloride paper has of late attracted a good deal of attention, and evidence upon the subject is consequently instructive. No, it was not P. O. P., for at the time the print was made no English paper of the kind was obtainable. I warmly welcome English enterprise in this direction, but I am fain to confess that we get a better article from the "beastly furriners" than our English firms supply us with at present. This need not and should not be. But I have said enough—perhaps too much—for this week.

CHATTERBOX.

## Letters to the Editor.

### HYDROQUINONE DEVELOPMENT.

SIR,—It was with great pleasure that I read the letter of "W. H. H.," in the AMATEUR PHOTOGRAPHER of the 9th inst., upholding the claim of hydroquinone to be a good developer.

It has always been somewhat of a mystery to me why so many among the presumed leaders in photography, including yourself and your predecessor, have always exhibited such a prejudice against hydroquinone as a developer, have invariably decried it, and, moreover, so persistently *misused* it. I say *misused* it because in all the experiments I have seen the results of published, bromide has been added to it, and bromide is the thing that is *not* wanted, is, indeed, most harmful, and destroys its power to a great extent.

I do not wonder at the mistake as regards what may be called the rank and file of photographers, as most of them cannot be expected to know much of chemistry, the scientific side of photography; but certainly as regards those who aspire to be teachers and leaders, we might expect better things.

Some two or three years ago the results of some experiments with eikonogen as a developer were published by Mr. W. K. Burton, and a more unscientific and rule-of-thumb procedure was never, I think, exhibited; it was, indeed, pointed out at the time by a writer in *Amateur Work*.

Did Mr. Burton, in his experiments, proceed to study the characteristics of this new substance, and the best way to develop its powers, if it had any? Most certainly not. He made up his usual developer with pyro, and then another exactly similar solution, only substituting eikonogen for pyro, and, developing two pictures with the different developers, he came to the conclusion that eikonogen was a failure—and well he might. Why did he not add some iron to the pyro solution? and then he would have found that a failure.

What would in any profession be thought of a teacher who, on a new drug being introduced for a specific purpose—say to reduce fever—could tell his class that he had given it a trial, had exhibited it in the same dose as some other drug already recognised as a febrifuge, and found it of no use? Suppose, for instance, the drug was antipyrine, which is given in 25 and 30 grain doses, and he had used it as quinine in 1, 2, or 3 grain doses, methinks he would not remain a teacher long.

Mr. L. Clark, in the book "Development," published at your offices, compares developers, and gives the results in exactly the same unscientific method. I quote, "The pyro acid was sulphopyrogallol, and the quinol was Byk's, and was made up *the same as the pyro* . . . . The restrainer used was invariably potassium bromide." To my mind this method of comparing developers is most wonderful, and can only attribute it to the want of any scientific training.

All new developers should, like new drugs, be judged on their own merits, and used in the way peculiar and best suited to their own individual powers, and not as older and well-known developers are used.

I have tried pyro in all ways, but as a professional man I much desired to find some developer that was not quite so dirty (nothing could be more so), and after three or four years' trial I maintain that if used rightly, for certainty, cleanliness, latitude of exposure, and, indeed, in every photographic requisite, hydroquinone and eikonogen are both preferable to pyro.

I always now use a formula given by Mr. H. Wilkinson in the AMATEUR PHOTOGRAPHER of July 25th, 1890, only substituting some hydroquinone for part of the eikonogen, and varying the proportions of eiko, hydro and alkali (potass. carb.) somewhat according to subject, but *not* using bromide. The only restrainer this developer wants, except under exceptional circumstances, is water. These exceptional circumstances are very great over-exposure, and possibly views with great distances, and then only a small quantity of bromide should be added, not more than  $\frac{1}{4}$  gr. to each ounce of developer. I do not myself use all fresh developer, an old developer-freshened with a little new I find gives the softest and most brilliant negatives, and if the developer is made with distilled water, or rain water caught off a clean roof in the summer when there are no blacks, and well boiled and filtered, it will keep any time. I have some made eighteen months since. It is colourless still, and the used developer keeps also any time if well corked and stored in the dark. As to the statement that latitude of exposure is greater with pyro than with hydro-eiko, I believe it to be unfounded.

I have sent you some photographs for your inspection. No. 1, intending to use stop  $f/22$ , omitted to alter Iris diaphragm, leaving full aperture  $f/8$ ; gave 2 sec. exposure, whereas by Watkin's metre, with  $f/8$ , should have had  $\frac{1}{4}$  sec. bare, eight times right exposure; old developer with three parts of water, and 1 gr. potassium bromide to each ounce—result, a ghastly failure.

Nos. 2 and 3, taken within ten minutes of each other, one  $f/8$ , the other  $f/22$ , both 2 sec. exposure; old developer, same quantity of water,  $\frac{1}{4}$  gr. bromide to  $3\frac{1}{2}$  oz. developer. Which is the  $f/8$  and which the  $f/22$ ? The other groups etc., will, I think, show that plates can be and are developed by hydro, eiko, or both combined, without hardness resulting. In 4 and 5 you will notice tube of shutter on the left, also in 6 going under my chair. No. 5 was developed with Burgoyne's new "lightning" developer—true to its name as far as time is concerned, the negative was developed rather under three minutes.

The only drawback that I can find with hydro or eiko-hydro is slowness, if it be a fault; time is necessary, from 15 to 30 minutes often being required, but then I do not mind that. A stained negative is a thing unknown with this developer, or fog of any kind, except from great over-exposure, or light other than that through the lens.

Can you tell me why I get such a very poor result on matt

surface paper—Scholzig—with platinum toning? I use soda after toning and a few drops of ammonia in the fixing bath.

For negatives I always use the acid fixing bath.—Yours truly,  
SURGEON.

[With regard to prints 2 and 3, which our correspondent asks us a question about, we should most decidedly say No. 2 was taken with *f/8*. Plain paper requires toning and fixing baths of half the ordinary strength. The whites in nearly every print sent by this correspondent are too hard, and he, quite unconsciously, furnishes us with another proof of the misuse of hydroquinone.—EDITOR.]

\* \* \* \*

#### SOCIETY FOR FOREST GATE.

SIR,—In reply to the query appearing in your last issue as to society for Forest Gate and Stratford. We are quite close to this district, and have a good number of members residing there. We have a roll of over ninety members, which speaks well for the success of the society. Our subscription is 5s. per annum. Our winter season commences in October. Informal meetings are held every Saturday evening at 8 o'clock at head-quarters, Assembly Rooms, High Road, Leytonstone, during this month, and we shall be pleased to see Mr. Wilton or any other gentlemen in the Epping Forest District, anxious to join a good society.—Yours faithfully, ALBERT E. BAILEY, Joint Hon. Sec.

Rose Bank, South West Road, Leytonstone.

\* \* \* \*

#### EASTMAN AND ILFORD P.O.P.

SIR,—Seeing the various letters from your correspondents anent the above, and particularly the communication from our mutual friend Mr. Welford, I have conducted a series of experiments in toning and fixing the gelatino-chloride papers of the two makes which are at present in the market. I find there is no need at all for a complicated toning bath or toning and fixing bath combined. The latter is particularly disastrous, by reason of prolonged immersion, which gives rise to stains and undue lightening of the colour of the print, while the tone produced by the original sulpho-cyanide bath is somewhat fugitive in the fixing bath, and, besides the possibility of the sulpho-cyanide being of questionable value, it rarely gives the same tone twice. Then again the whites of the prints require to be kept unstained; this can only be obtained by a fairly quick toning process, and I claim for my bath that this is peculiarly characteristic. The formula is as follows:—

Acetate soda .. .. . 1 dram.

Phosphate soda .. .. . "

Carbonate soda (common washing soda) .. .. . "

Dissolve in 20 oz. warm water, and add 3 gr. chloride gold.

In this bath the prints tone in 10 minutes, or in the case of deeply printed proofs 15 minutes, and the tone, while slightly suffering in the fixing, is all that can be desired, and if any of your readers would like to see what it does in my hands and will send me a halfpenny stamp, I will send a specimen. I enclose specimen print for your observation.

For fixing bath I use the ordinary solution of hypo soda, 3 oz. to the pint, with 2 oz. of the above toning solution to the pint; this addition prevents the colour being "robbed" by the fixing solution.—Yours, etc.,  
H. PICKERING

(Hon. Sec., Leicester Photographic Society.)

[The print sent by our correspondent is a very pleasing purplish brown with pure whites, and no signs of unequal toning.—EDITOR.]

\* \* \* \*

#### A NEW ALBUM WANTED.

SIR,—I am writing to you to ventilate a grievance which it seems to me requires now a remedy. I refer to the question of suitable books in which to mount photographs. The present ones seem to me unworthy of the position which photography has attained, while the market is inundated with mounts of very kind of quality and artistic excellence, for manufacturers seem to vie with each other in turning out really beautiful supports for the different classes of prints; yet we do not, I venture to say, find the same when we look at the so-called books in which we are asked to place our prints. They are mostly of white or greyish colour, and if the object of a mount is to enhance the beauty of a print, besides being merely a support, you will not obtain your wish by placing it on one of the pages of the ordinary books. And if through the medium of your excellent paper influence could be brought to bear, I feel sure some of our big houses would turn their attention to this subject, which appears to me so neglected, and issue small and large

books, with plate-sunk mounts, say, and india-tint borders, and in other ways rendering these books more suitable for the reception of platinotype, bromide, and other prints.—Yours, etc.,  
P. G. BULL.

## General and Photographic Chemistry.—VII.

By E. C. CONRAD, F.C.S.

### THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.—(Continued).

NITRIC ACID,  $\text{HNO}_3 = 63$ .—Oc.: In India, Peru, and other places, deposits of nitrates are found, produced by the action of atmospheric electricity on the oxygen, nitrogen, and aqueous vapour of the air and the action of the nitric acid formed on the alkaline substances contained in the soil. Thus in South America large deposits of sodium nitrate are found, called commercially Chili saltpetre, to distinguish it from potassium nitrate, also called saltpetre or nitre, the principal deposits of which occur in Asia and Spain. M.: By distilling a mixture of potassium nitrate with strong sulphuric acid. Eq.:  $2\text{KNO}_3 + \text{H}_2\text{SO}_4 = \text{K}_2\text{SO}_4 + 2\text{HNO}_3$ . Commercially, sodium nitrate is used instead of the potassium salt, because it is cheaper and a given weight produces a larger quantity of the acid, the molecular weight of sodium nitrate  $\text{NaNO}_3$  being 85, while potassium nitrate,  $\text{KNO}_3$ , is 101. The operation is carried on in an iron retort lined with fireclay, and the acid condensed in earthenware jars. The reaction really takes place in two stages, an acid sulphate being first produced and this decomposing another molecule of the nitrate thus, (1)  $\text{NaNO}_3 + \text{H}_2\text{SO}_4 = \text{NaHSO}_4 + \text{HNO}_3$  and (2)  $\text{NaNO}_3 + \text{NaHSO}_4 = \text{Na}_2\text{SO}_4 + \text{HNO}_3$ . P.: The pure acid is a colourless, strongly fuming liquid of S.G. 1.5. It generally has a yellow colour, due to the presence of oxides of nitrogen, from which it can be freed by a current of air. It freezes to a buttery mass at  $-55^\circ$ . On heating, the strong acid is gradually decomposed until it possesses a S.G. of 1.4 at  $15^\circ$ , equal to 68 per cent. of acid when it distils over unchanged. A weak solution boiled under the ordinary pressures gradually becomes concentrated to the same proportion of acid and water. At a temperature of  $260^\circ \text{C}$ . nitric acid is decomposed into nitrogen tetroxide,  $\text{N}_2\text{O}_4$ , water and oxygen. Nitric acid parts with a portion of its oxygen with great readiness, and is therefore an oxidising agent of great power; phosphorus, sulphur, charcoal, and some of the metals are oxidised, the colour of indigo discharged, and the skin stained yellow by it. Nitric acid is miscible with water in all proportions.

*Action of Nitric Acid on the Metals.*—Aluminium, gold, and platinum are not acted on. Arsenic, antimony, and tin are oxidised to white powders  $\text{As}_2\text{O}_3$ ,  $\text{Sb}_2\text{O}_3$ ,  $\text{SnO}_2$ . All the other most important metals easily dissolve, forming nitrates. When nitric acid acts on a metal, hydrogen is never set free, but the oxides of nitrogen and free nitrogen are given off.

*Action of Heat on the Nitrates.*—Heat reduces the nitrates to an oxide of the metal with evolution of oxides of nitrogen and oxygen. Thus calcium nitrate,  $\text{Ca}_2(\text{NO}_3)_2$ , on being heated forms calcium oxide,  $\text{CaO} + \text{N}_2\text{O}_4 + \text{O}$ . The nitrates of mercury and silver are reduced to the metallic state at comparatively low temperatures.

*Tests.*—If nitric acid or a solution of a nitrate is added to a strong solution of ferrous sulphate, and a small quantity of strong sulphuric acid is carefully added so as not to sensibly raise the temperature, a brown ring will be formed.

All the nitrates are soluble in water. Nitric acid stains woollen fabrics red, and this colour is not removed by ammonia like that caused by sulphuric and hydrochloric acids.

*Uses.*—Nitric acid is largely used in manufacture, especially for the production of nitrate of silver and gun cotton, pyroxilin and other nitrated cellulose compounds.

**OXIDES OF NITROGEN.**—The following compounds of oxygen and nitrogen can all be obtained by indirect means from nitric acid, and they all have a tendency to combine with water and oxygen to reform that acid. They are—Nitrous oxide,  $N_2O$ ; nitric oxide,  $N_2O_2$ ; nitrous trioxide,  $N_2O_3$ ; nitric peroxide,  $N_2O_4$ ; nitric pentoxide,  $N_2O_5$ .

*Nitrous Oxide*, or nitrogen monoxide,  $N_2O$ .—M.: By the action of dilute nitric acid on zinc. Eq.:  $4Zn + 10HNO_3 = 4Zn(NO_3)_2 + 5H_2O + N_2O$ . P.: Colourless gas, liquid at a pressure of 30 atmospheres. It is easily decomposed by heat, and the liberated oxygen supports the combustion of such bodies as a glowing splint, burning phosphorus, or other substance that gives out sufficient heat to decompose it. It is very soluble in water, and gives no red fumes with  $N_2O_2$ . It is distinguished from oxygen by these last two properties.

*Nitric Oxide*, or nitrogen dioxide,  $N_2O_2$ .—M.: By the action of nitric acid on copper. Eq.:  $3Cu + 8HNO_3 = 3Cu(NO_3)_2 + 4H_2O + N_2O_2$ . P.: Colourless gas; when exposed to air it immediately unites with the oxygen, giving red fumes of  $N_2O_3$  and  $N_2O_4$ . Insoluble in water, more stable than  $N_2O$ , requires a high temperature for its decomposition; burning phosphorus will do so, and continue to burn in the liberated oxygen. If nitrous or nitric oxides are passed over red-hot copper an oxide of the metal is formed and nitrogen gas set free.

*Nitrous Trioxide*, or nitrogen trioxide,  $N_2O_3$ .—M.: By the action of nitric acid on arsenious oxide. Eq.:  $As_2O_3 + 2HNO_3 = As_2O_5 + H_2O + N_2O_3$ . P.: A reddish-brown gas, soluble in water, forming nitrous acid,  $N_2O_3 + H_2O = 2HNO_2$ . It is converted into a blue liquid on exposure to cold. This oxide is of importance in the manufacture of sulphuric acid.

*Nitric Peroxide*,  $N_2O_4$ .—M.: By the decomposition of lead nitrate by heat. Eq.:  $2Pb(NO_3)_2 = 2PbO + O_2 + N_2O_4$ . Also by the union of nitric oxide with oxygen. P.: A reddish-brown gas like the trioxide, soluble in water, forming a mixture of nitrous and nitric acids; hot melted potassium burns in it. When perfectly dry it forms a white crystalline compound.

*Nitric Pentoxide*,  $N_2O_5$ .—M.: By passing dry chlorine gas over dry silver nitrate. Eq.:  $4AgNO_3 + 2Cl_2 = 4AgCl + O_2 + 2N_2O_5$ . P.: It is a colourless crystalline compound, very unstable. With water it produces nitric acid,  $N_2O_5 + H_2O = 2HNO_3$ .

**NITROUS ACID**,  $HNO_2$ .—O.: Nitrites are found in water contaminated with sewage, and the acid in the water produced by the combustion of hydrogen in the air. M.: By the combination of nitrous trioxide with water. P.: The acid itself is very unstable, and it forms a series of somewhat unstable salts, termed nitrites. *Tests*: Solid nitrites warmed with dilute hydrochloric acid give brownish-red fumes. Dilute sulphuric acid and solution of ferrous sulphate give with solutions of nitrites a brown colouration. Nitrites can be distinguished from nitrates by giving with dilute sulphuric acid and solutions of potassium iodide and starch a blue colour.

**HYDROXYLAMINE**,  $NH_2OH = 33$ .—M.: By the action of nascent hydrogen upon nitric oxide. This base cannot be obtained pure, is known only in solution, is very volatile and easily decomposed. Hydroxylamine hydrochloride,  $NH_2OH, HCl = 69.5$ . M.: By passing a current of nitric

oxide into a series of flasks containing tin and hydrochloric acid with a small quantity of platinum tetrachloride solution (to facilitate the evolution of hydrogen at the ordinary temperatures). The solution is then purified by precipitating the tin with sulphuretted hydrogen, filtering and evaporating to dryness, and washing the salt with strong alcohol. P.: Easily soluble crystalline compound; the solution of this salt does not oxidise by exposure to the air. U. P.: As a developer. Messrs. Egli and Spiller, who first introduced it, recommend the use of equal parts of the carbonates of soda and potash as an accelerator, while Chapman Jones gives the following formula:—

Hydroxylamine hydrochloride	..	..	2 gr.
Caustic soda	..	..	3 "
Potassium bromide	..	..	$\frac{1}{2}$ "
Water	..	..	1 oz.

It gives with gelatino-bromide plates a black image, free from stains, and allows of slightly over-exposure without injury. *Tests*: Hydroxylamine and its compounds give with copper sulphate a green precipitate, and on warming this red copper oxide is thrown down.

## Reviews.

*Fotografisk Tidskrifts Arsbok*, 1892. Published by Albin Roosval, Stockholm.

This annual visitor, which emanates from the office of the *Fotografisk Tidskrift*, is handsomer than ever. It contains numerous articles by well-known writers, a summary of photography, and is characterised by the beauty of its illustrations, which include no less than three photogravures, four collotypes, one chromotype, besides numerous process blocks, and a matt chloride cloud print of great beauty.

*Practical Guide to Photographic and Photo-mechanical Printing Processes*. By W. K. Burton. Second edition. Published by Marion and Co., 22 and 23, Soho Square, London, W. Price 4s.

This work has long been one of the standard works, and we can heartily welcome the second edition, which has been considerably enlarged and revised. The first part of the book is devoted to an historical sketch of photographic and photo-mechanical printing. The second part to ordinary printing-out processes, such as silver, platinotype, iron and uranium processes, bromide and carbon work. Comparing this with the previous edition we find considerable revisions and additions even with this part, but that part of the work devoted to photo-mechanical work has been entirely re-written and remodelled, and now forms a useful and complete practical handbook.

The work is well printed and neatly bound, and should be welcomed by the tyro as well as the more advanced hand.

## Catalogues.

YORK AND SON, 67, Lancaster Road, Notting Hill, W.

This well-known firm of lantern slide manufacturers have sent us their twenty-third annual supplemental catalogue of new lantern slides and lecture sets, of which a brief synopsis is given. After having occupied their premises for twenty-nine years, this firm have now moved into more commodious premises at No. 67, Lancaster Road.

G. W. WILSON AND CO., of 2, St. Swithin Street, Aberdeen.

List of Studies by Frank M. Sutcliffe.

F. M. Sutcliffe has long held one of the premier positions as an artistic worker, and Messrs. G. W. Wilson and Co. are now issuing a series of 12 by 10 studies executed in carbon of all colours at the low price of 3s. 6d.

NEW LANTERN SETS.

This firm also sends us a catalogue of the new slides they have added to their well-known series. These include travels through Europe, Africa, Egypt, New Zealand, etc.

## ILLUSTRATED SUPPLEMENT,

## Monthly Competition, No. 39, "Sea Pieces and River Scenery."

**W**HILST this Competition has not been quite so heavy in numbers, we have to congratulate ourselves and our competitors on having sent in far better work, as a whole, than we have had in previous Competitions. The task of deciding which were to be the first three prints was no easy matter, and the judges meanly suggested that the easiest way out of the difficulty was to give the first six competitors a Silver Medal each, the next six a Bronze Medal each, and certificates to the remainder of the first-class. Unfortunately, we could hardly fall in with this suggestion, but we have awarded an extra certificate, the judges declining to separate two competitors.

Taking the work as a whole, we have no hesitation in saying that many of the competitors whose work is this time placed in the third class would in previous Competitions have been amongst the second class. And whilst to these competitors the result may be disappointing, to us the result is extremely gratifying. Our Competitions are intended for the improvement of work, and we hope that this Competition will be the commencement of a period of improvement.

The quality of the work sent in, and included in Classes I. and II., is so nearly equal that, with the exception of the first six pictures, we are unable to place them in the order of merit.

## CLASS I.

1. POLLOCK, J. A. (Belfast).—"A Good Start." Taylor and Hobson's R. R.,  $f/16$ ; 1-80th sec., July, good light, mid-day. "This shot was taken with the camera in the hand; no stand used." A whole-plate chloride print, full of life and motion, and with a very effective sky.

2. LEES, H. (Didsbury).—"In Chee Dale." Suter 3 B Aplanat,  $f/45$ ; 20 sec., October, fair light, 2 o'clock. A whole-plate, rough-surface bromide print, of exceptionally fine technique.

3. WILLIAMSON, J. (Hove).—"Trawlers off Brighton." Taylor and Hobson's R. R.,  $f/11$ ; 1-5th sec., May, hazy sunlight, 7 a.m. "This was taken from small rowing boat." A 5 by 4 rough bromide print, toned with uranium; in appearance this print is far more like a very good sepia drawing or etching.

3A. RICE, W. (East Dulwich).—"Barges on the Thames." Ross's R. R.,  $f/16$ ; 1-10th sec., June, sunshine, noon. A 5 by 4 chloride print, of exceptional brilliancy and pluck. The competitor was un-

usually fortunate in being able to obtain so clear an atmosphere in the heart of the city.

4. TIMMINS, J. C. A. (Runcorn).—"Eventide." R. R. French,  $f/11$ ; seascape ( $f/32$ ) 2 sec., cloud about 1 sec., April, good diffused light. "The above negative is composed of two negatives, seascape and clouds." A 9 by 7 chloride print, and really suggestive of evening, not overdone in printing, and yet sufficiently low in tone to give the desired idea.

4a. WILCOX, W. (Fulham).—"Waiting at the Lock." Optimus R. R.,  $f/32$ ; 1 sec., June, bright sunlight, but very cloudy, 10 a.m. "I waited a long time with a chance of a boat coming along, and was at last rewarded. First time of entering any competition." A

half-plate silver print, which might have had just a little less foreground. It will be noted, by the shadow of chimney on house, that the lighting is quite in front, and a very successful result has been obtained.

5. ASHBURN, W. D. (Bromsgrove).—"Early Morning on the Clyde." Taylor and Hobson's R. R.,  $f/22$ ;  $\frac{1}{2}$  sec., April, diffused light, misty, 8 a.m. "Taken from the deck of the Liverpool steamer on arrival at Greenock, the mists rolling down the river with occasional gleams of sunlight." A 6 by  $3\frac{1}{2}$  platinotype print, and one of the very finest effects of a misty morning we have seen.

5a. DUNCAN, A. H. (Glasgow).—"On the Clyde." Taylor and Hobson's,  $f/8$ ; 1-10th sec., August, weak sunlight, 8

No. 1.]

"A GOOD START."  
SILVER MEDAL.

[J. A. Pollock.

o'clock. "Taken from one of the Cluthas in Glasgow harbour, H.M.S. *Gibraltar* on the left, and a large four-masted vessel, the *Cedarbank*, in the channel, being towed down with tug in front and tug behind to steady her. This characteristic view was obtained quite unexpectedly." Another Clyde view, but in its character quite as good as the one above.

GOLDING, A. J. (Tufnell Park).—"Eventide, Strand-on-the-Green." Beck's R. R.,  $f/16$ ; 2 sec., August, diffused light, 6 p.m. A very clever  $5\frac{1}{2}$  by 4 study on matt chloride paper, which strongly recalls one of the collotypes in our "Annual."

MACADAM, D. (Haltwhistle).—"Derwent Water." Hockin's Wide-angle Rect.,  $f/32$ ; 3 sec., June, bright sunshine. A whole-plate matt chloride print of very fine technical work, and with a charming rendering of distance.

UFFINDELL, F. (Finsbury).—"Mouth of the River Yare. Smacks being Towed out to Sea." Hockin and Wilson's R. R.,  $f/16$ ; drop shutter, July, dull, 11.30; taken from Gorleston Pier. A very good half-plate chloride print full of motion.

JONES, W. L. (Sale).—"In Bolton Woods." Wray's R. R.,  $f/20$ ; slow shutter, bright sunshine, midday. "This view was taken last Easter whilst on a walking tour in Yorkshire, and by a hand-camera of my own construction." A good proof that artistic work may be done by a hand-camera.

EYRE, H. S. W. (Crowboro').—"Placid Waters." Landscape lens,  $f/30$ ; 8 sec., August, dull, 5 p.m. A half-plate silver print of

good quality, the only offending bit being the leaves in the right-hand corner.

ANDERSON, E. (Newcastle-on-Tyne).—"Sunshine after Rain." Single lens,  $f/32$ ;  $\frac{1}{2}$  sec., July, brilliant sunshine, 3 p.m. "Taken immediately after a heavy shower." A half-plate matt-surface chloride print of rich, warm tone, with a very fine sky.

HIRST, E. (Cleckheaton).—"Douglas Bay, Isle of Man." Half-plate view,  $f/20$ ; cap on and off, June, bright sun shining, 11 a.m. "This view was taken from the sea on a half-plate. It is a contact print, the clouds being in the negative." A little narrow strip of a picture measuring 6 by  $2\frac{1}{2}$ , slightly over-printed, but very effective.

TIMS, J. (Ewell).—"Closing the Lock Gates." Optimus Eury-scope,  $f/16$ ; 1-10th sec., August, sunshine, blue cloudless sky, 3 p.m. "This lock is on a tributary of the Thames." A very good half-plate platinum print, full of softness and detail.

GLAZEBROOK, T. (Ashton-under-Lyne).—"Time and Tide wait for no Man." Dallmeyer stereoscopic lens,  $f/16$ ; slow shutter, July, diffused light, 6 o'clock. "Taken at Port Erin, Isle of Man." A quarter-plate matt chloride print, and a very effective arrangement of light and shade.

BECKWITH, W. (Leeds).—"Pull's Ferry, Norwich." French R.R.,  $f/22$ ; 1 sec., August, bright sun with white clouds, 10 a.m. "I only began the fascinating pastime last summer. Negative and print absolutely untouched." Half-plate matt chloride print, just wanting in brilliancy.

GROVES R. (Blandford).—"White Cliff Mill, Blandford." R.R.,  $f/16$ ; 1 sec., June, bright light, noon. A very pleasing spot, but spoilt by a little too much foreground and the pink tinge of the paper.

BROWN, W. A. M. (Leeds).—"Meeting of the Waters, Bolton Abbey." Ross R.S., 50 sec., August, dull and hazy, noon. This is a platinotype of unusual size, 25 by 22. Technically the print is very fine, but it could be improved by cutting about three inches off the top and bottom, and by printing in clouds.

## CLASS II.

SOLTAU-SYMONS, G. (Plympton).—"The Ebbing Tide." Ross, R.S.,  $f/32$ ; 2 sec., July, bright, 5 p.m. A  $9\frac{1}{2}$  by 7 chloride print with a very fine sky, but the horses, cart, and man are right in the centre of picture.

BALL, F. R. (Clapham).—"Lowestoft Harbour." Single lens,  $f/10$ ; June, bright light, 1 p.m. "Taken from the pier at Lowestoft, as the smack was going out of harbour." A half-plate sepia platinotype, of very great softness.

ATKINS, R. (Waterford).—"The Nord Fjord, Norway, from Faleide." Optimus R.R.,  $f/32$ ; 10 sec., July, wet day. "The view is taken from the grounds of Tenden's Hotel at Faleide on the northern shore of the Fjord, and looks away towards the mountains, enclosing the Buxtal and Kjendalo glaciers." This is a whole-plate matt chloride print, the subject being very fine, but spoilt by unequal toning.

VULLIAMY, E. P. (Glasbury).—"Three Cliff Bay." R.R.,  $f/20$ ; shutter, June, dull afternoon. "The wind was so strong that the camera shook, and only shutter exposure was possible." A whole-plate bromide; a very good effect of a rocky shore, suggestive of storms.

GOSLING, G. (Hornsey).—"On the Colne." R.R. lens,  $f/22$ ; 2 sec., June, sunlight, 1 p.m. A half-plate platinotype print of good technical quality.

LUDDINGTON, L. H. (Littleport).—"St. John's College Chapel, Cambridge." Dallmeyer R.R.,  $f/24$ ; 1 sec., August, good sunlight, 3 p.m. "Taken from the river at The Backs. The plate being a thick coated one, I was rather puzzled to know when development had been carried far enough, and consequently the negative is

rather thin." Half-plate platinotype, with far too much foreground.

SEEVERS, J. (Kendal).—"On the Kent." Ross' single,  $f/15$ ; 3 sec., August, bright light, noon. A charming little quarter-plate platino study, bright, and full of sunshine.

ALCOCK, F. (Twickenham).—"A Desolate Spot." Ross' Orthographic,  $f/22$ ; 1 sec., August, sunlight, 6 p.m. "South side of the Island of Portland, Dorset." A whole-plate platinotype, and a very good carrying out of the title.

ROSSER, C. W. A. (Malta).—"At Head of Quarantine Harbour, Malta." Single lens,  $f/16$ ; 1-20th sec., February, sun behind thin cloud, nice soft light, 8 a.m. "Plate required most careful development. The negative resulting was too weak to print from, but after intensification produced a nice density." By no means a bad little half-plate print, but there is just a little too evident arrangement.

LEWIS, A. H. (London).—"Durham Cathedral, taken from the Wear." Optimus R. R.,  $f/32$ ; 2 sec., July, bright, 3 p.m. "Previous to exposing, it threatened to rain, but cleared off, and after waiting three-quarters of an hour, exposed under a blue sky." A very good half-plate view of a well-known spot, slightly wanting in brilliancy.

KINGSFORD, R. L. (Gt. Malvern).—"The Church Pool on the River Conway, Bettws-y-Coed." Single landscape lens,  $f/22$ ; 2 sec.,

August, diffused light, 6 p.m. "A half plate platinotype print of a very pretty spot, utterly spoilt by two incongruous figures.

TYLEE, C. (Shoreditch).—"Eel Sniggling." R.R. lens,  $f/32$ ; 3 sec., May, good light, 10 a.m. A whole-plate chloride print of a hideous pink colour, and the eel sniggler is the least important thing in the picture.

THOMPSON, H. (Harrogate).—"Pont Newydd, Aber, N. Wales." Laverne, R.R.,  $f/25$ ;  $1\frac{1}{2}$  sec., July, dull and overcast, 11.30 a.m. "Taken on a very windy day after heavy showers, and only moderate light. Sun nearly obscured." A quarter-plate silver print which has been spoilt by over-printing.

GAPE, C. (Scole).—"Syleham Mill, on the Waveney." Swift's Rapid Paragon,  $f/22$ ; 6; 1 sec., August, sunshine, 1 p.m. A quarter-plate silver print of a pretty spot, spoilt by over-printing.

SUTHERLAND, J. W. (Newcastle-on-Tyne).—"Oddicombe Bay, South Devon." Optimus,  $f/16$ ; shutter, April, bright light, mid-day. A half-plate matt-surface chloride print, showing careful work.

ELPHICK, E. J. (Hastings).—"Landing the Night's Catch." Lancaster's R. R. lens,  $f/16$ ; shutter, June, rather dull light, 6 a.m. A half-plate chloride print, rather over-printed.

TOWNSEND, C. J. W. (London, S.E.).—"On the East Lyn, Lynton, North Devon." Optimus R. R.,  $f/32$ ; 4 sec., June, sunlight, 1 p.m.

"I had no choice as to the time of day, as my stay at Lynton was only about three hours. The light being very bright; sun almost shining in lens." A very pretty little quarter-plate study.

RITCHIE, D. (Edinburgh).—"On the Tweed, near Peebles." Taylor and Hobson's R. R.,  $f/16$ ;  $1\frac{1}{2}$  sec., July, bright sunshine, 4 p.m. "The print was dried on ground glass, and mounted when dry." A good half-plate picture, spoilt by the hideous pink tint.

NETTLESHIP, T. W. (Bawtry).—"Sprotborough Mill on the Don." Optimus R.R.,  $f/32$ ; 3 sec., May. Moderately good light, setting sun, 6 p.m. A half-plate chloride print, which has yellow whites and is slightly overtoned.

EALLEN, J. (Sheffield).—"Bridlington Harbour." Ross's R.R.,  $f/8$ ; 1-30th sec., June, sunshine, 3 p.m. A whole-plate chloride print, which could be considerably improved by trimming.

WIGHTMAN, G. J. (Lewes).—"Rocky heights that overlook the breadth of ocean." Taylor's R.R.,  $f/12$ ; shutter, sunlight, with very slight haze, 11 o'clock. "Taken quickly, in order to include a flock of gulls." A whole-plate platinotype print, which would be improved by suitable clouds.

No. 2.]

"IN CHEE DALE."

[H. E. Lees.

11 ROY ZE MF DAL.

DUNKERLEY, V. (Burnley).—"Scene near Vix, Norway." Reynolds'  $3\frac{1}{2}$  focus,  $f/32$ ;  $\frac{1}{2}$  sec., July, brilliant light, noon "Distance remarkably clear, water clear and formed powerful reflector." A quarter-plate chloride print of good technical quality, utterly spoilt by the pink colour of paper.

GAINE, R. L. (Sunderland).—"A Misty Evening in the Derwent Valley." R.R. London and Paris Optical Company,  $f/32$ ; 18 sec., June, very dull light, 7 p.m. "Rain was commencing just as exposure was made." Print good technically, and a pretty spot

BANKS, J. F. (Norwich).—"Thorpe, River Yare, near Norwich." Beck's R. R.,  $f/22$ ; 1 sec., July, sun behind cloud, just breaking through, 11 a.m., "Thorpe, on the River Yare, about two miles from Norwich, and on the Yarmouth Road. Taken from Hart's boat-house, looking towards Norwich." A half-plate silver print, not from the very best point of view, for this spot.

ARNOLD, J. O. (Sheffield).—"Conway Quay." Wray's R. R.,  $f/32$ ;  $\frac{1}{2}$  sec., July, strong sunshine, 4 p.m. "A very large Norwegian brigantine had hauled into the Quay, and was taking in ballast. The sails had been shaken out to dry, and the order was just given to furl—hence the half-furled royal." A brilliant half-plate matt-surface chloride, showing very good work.

BROWN, A. (Liverpool).—"Evening on the Mersey." Eureka R. R.,  $f/16$ ; shutter, June, bright light, sun behind cloud, 6 p.m. A half-plate chloride print, of which we venture to suggest the improvement that might be effected if the sky-line was straight, and the whole not printed so deep.

BARCLAY, H. (Salisbury).—"The Golden Evening Brightens in the West." Lancaster's rectigraph,  $f/16$ ; shutter, June, good light, shortly before sunset. A half-plate silver print of a pleasing subject, which we think would be far better on rough-surface paper.

MACKENZIE, J. G. S. (Edinburgh).—"Currie, on Water of Leith, near Edinburgh." Taylor and Hobson's R. R.,  $f/32$ ;  $1\frac{1}{2}$  sec., July, sunlight, 3 p.m. A half-plate chloride print, just wanting in brilliancy.

**Commercial Potassium Cyanide.**—According to the *Chemiker Zeitung*, 1892, No. 64, Dr. Klayser, of Nuremberg, read a paper on this subject before the eleventh meeting of the Free Association of Bavarian Representatives of Applied Chemistry. The kinds of potassium cyanide at present generally met with in commerce consist generally of a mixture of potassium cyanide and sodium cyanide. If we simply determine the quantity of cyanogen, and calculate the result as potassium cyanide, a commercial sample containing 15 per cent. impurities may easily be reported as potassium

cyanide of 100 per cent. The presence of considerable quantities of potassium cyanide is further not indifferent in many technical applications. Thus in preparing galvanic gold baths from gold as anode in a solution of potassium cyanide and sodium cyanide, by means of the galvanic current, there is obtained not a readily soluble sodium auro-cyanide, but a very sparingly soluble sodium auro-cyanide. But its origin is at once deposited on the anode, and we do not succeed in obtaining a useful gold bath. In the view of the speaker it is possible that the advice of Wagner has been followed in the manufacture of ferro-cyanide. Wagner, mainly from technical reasons, recommended the use of a mixture of potash and soda, and that the resulting mixture of potassium and sodium cyanides should be sold under the name of cyanogen salt. Professor Fresenius confirms the presence of sodium ferro-cyanide in the potassium ferro-cyanide of commerce.

**Dark-room at Lowestoft.**—Mr. Clark, chemist, of S. Lowestoft, has fitted up a dark-room which is free to customers for changing and for developing, at the price of chemicals only.

**Darlington.**—The monthly meeting was held on the 12th inst. Mr. Ensor presided in the absence of the President. Mr. J. G. Sinclair read a most interesting paper on the "Platinotype Process," illustrated by some beautiful prints from his own negatives. Mr. Sinclair concluded a most instructive paper by developing some prints by means of the cold-bath process, which were very successful.

## The Office and the Future of our Exhibitions.

By A. HORSLEY HINTON.

PHOTOGRAPHY has for some time past been advancing strong claims to recognition as an art proper, and with a measure of success. Many of the most able workers in photography have logically enough shown why such recognition should no longer be withheld, and their persuasions and arguments have convinced some and have brought very many others to half acknowledge that which they before ridiculed. It will, however, have occurred to many that if the really artistic be possible by photographic means, then it should of itself be sufficiently apparent, and all the writing and the hours of talking which have been expended in pleading its cause should be wholly unnecessary.

We have, however, to remember the exceptional position in which photography is placed—a position which has made it imperative to separate it from its antecedents, and to set it upon a new footing, apart from all old associations.

The photographer who employs the accepted methods but purely with an artistic aim, is under the necessity of saying that the particular kind of performances which he advances as a new means of artistic expression is not photography as generally known and accepted as the work of camera and lens, but the particular description of work which has resulted from the use and modifications of photographic implements in the hands of men of natural artistic instinct.

Never, then, has there been so urgent a need unsatisfied—a need of a new name which whilst recognising the means whereby the results are obtained shall at the same time adequately distinguish the photographs which have as their aim purely the attainment of an artistic ideal from the average mechanical work which is produced by those who use the apparatus only as a machine, and who do not attempt, do not desire, and, perhaps, could not if they would, import anything of individuality, of sentiment, or personal expression into visible results of the employment of photographic methods.

It is not sufficient to describe these latter as dilettante, it is not the triviality of purpose that prevents, for in them there may be a very sincere and earnest purpose, but rather that the purpose is of a distinct and different order, and possibly lacks elevation and dignity, and which, even when zealously pursued to its utmost, will be transient in effect or even ignoble. We have ever the want of some descriptive term by which to distinguish between the photography which illustrates the wonderful capabilities of the instrument, and the photography which illustrates the artistic mind, or, in other words, succeeds in expressing an idea or a group of associated ideas, in the imagination of the artist, the ideas themselves but an impression received from some scene in nature.

We have engraving, and etching, and mezzotint, and photo-

graphy—each a possible means of artistic expression if used aright according to their varied methods—and whilst the three former are universally admitted as art, the latter still occupies a very unsatisfactory position, a state of purgatorial transition, until such time when it shall have been purged of its old failings and adapted for a higher sphere.

With those who have lived amongst photographers, becoming intimately acquainted with their widely different work, and are open-minded and without bias, some may be found ready to recognise the art claims of the more advanced of modern photographic pictures, and will agree that those examples of photography produced by intelligent and essentially artistic men do demand a judgment and consideration quite apart from the great mass of photographs with which the world has become inundated, and must individually be admitted as equal to many, and superior to some, of the results produced by contemporary monochrome methods.

But to the general public, and even to the cultivated classes, photographs are still photographs, and, no matter how excellent

or how satisfactory, are still regarded not as pictures in any sense, but at best with the same feeling as curiosities and souvenirs of travel and place.

We encountered the effect of this prejudice in a practical form quite recently when in conversation with a well-known picture dealer in London.

Noticing among the water-colour drawings and paintings in the small gallery a few mezzotints, we tested our picture dealer's knowledge of modern photography, and was pleased to find that he was well acquainted with some of the most modern developments of artistic photography; and on being asked, he admitted that in some cases he should prefer them to mezzotints which he considered they somewhat resembled. He believed that were he to show them they would attract the attention of his clients and visitors, and yet it would be useless for him to offer them for sale, because on being asked what they were he had no alternative but to call them "photographs," and he should expect his customer to turn his back upon them in consequence, and he himself would lose caste as a "dealer in works of art."

The position is indeed a sorry one; it is a case of popular prejudice paralysing the endeavours of a thoroughly sincere school of artistic workers, a possible fine art crippled in its efforts to assert itself by the abundant misuse of its methods, and its best and legitimate results condemned unheard because of the multitude of worthless productions under the same name and title which have preceded them. The false light in which art photography is generally seen, and the universal misappreciation from which it suffers, is, we believe, to no small extent attributable to the circumstances under which photographs collectively are publicly shown such as in our exhibitions. The more important the exhibition the greater its influence, and the greater the responsibility which devolves upon those who direct it and lay down the lines for its management.

From the Club exhibition, which is confined to the works of its

CERTIFICATE.

own members, to the International exhibition, which makes its walls available to all, whether professional or amateur, whether of this country or of any other, in each case the exhibition is the direct means of communicating to the outside world substantial evidence of the progress and capability of that which is exhibited. It is reasonably supposed that such an exhibition is

graphers can do. Was there ever a parallel to such a picture exhibition? What must be the inevitable result? What but that for every photograph of real merit there are twenty which are indifferent or even bad, and the impression which the few good things have upon the visitor's mind is overwhelmed and obliterated by the impression produced by the innumerable inferior works? Little wonder that the general and popular notion of photography is so erroneous and misled.

Elsewhere than in London this unsatisfactory condition of affairs has been already appreciated, and to some extent has been met. The help of known and successful photographers has been asked, and exhibitions of what might be regarded as the best and most modern of photographic picture work have been held; but in this country, where admittedly artistic photography has been carried to its greatest height, no such just and intelligent means of educating public opinion and advancing the new art has been afforded us, and it has been left to a private club to take the initiative. This year the London Camera Club has decided to devote its room to the purpose of exhibiting a limited collection of carefully selected works of known photographers. All honour and thanks to the Camera Club for this first step in the right direction, and especially to those men in whom the idea originated. But it is not enough. An exhibition held within the premises of a private club must, be it ever so "open" in character, have a limited application, and can only touch a restricted circle; but it is a step in the right direction, and one which, surely enough, will not be without a following,

and probably ere photography is a year older the combined action of the many who have long felt the imperative need of reform will result in the organisation of some such exhibition in London as Vienna and Brussels have already attempted before us.

We say this in no spirit of prophesy, for no one who has watched the progress of things, who has, so to speak, felt the

'EVENTIDE.'

[J. C. A. Timmins.

thoroughly representative of the best contemporary work, and is hence the means whereby the public forms its estimate—not the general public only, but also such particular sections of it who are really interested, and who probably go to examine the quality and character of the exhibits for special purposes, and with definite object in view. To a well-appointed photographic exhibition it may be sometimes possible to allure those whose opinion may be worth having, but who would never be at the trouble of searching out for themselves and ascertaining the true merits of more or less isolated and obscure artists, or who would never pause to seriously consider what possibilities might be in the future for photography. Hence we believe the exhibitions are our most powerful instrument in advancing the higher art claims of photography outside the circle of the cognoscenti.

To be sure, public opinion, some may say, is not worth having, and that we need not seek to cultivate its approbation. This is true, no doubt, to a great extent, yet by public opinion we do not necessarily mean the opinion of the cultivated, and the great humanity to whom anything outside the immediate necessities of daily life never appeals; but there is a public which for us may include the painter, the sculptor, the poet, and the writer of contemporary history, and whosoever may be concerned in the intellectual or æsthetic development of the times.

Each individual worker may assist in elevating the position of photographic art, but the effect is infinitesimal as compared with the concerted effort of many exhibitors at one time; and this being so, the desirability of having an exhibition of photographic pictures wherein every contribution shall possess peculiar and individual merit, which shall constitute a reason for its being exposed to public view, and be in itself a testimony of the higher possibilities, well be at once apparent.

Hitherto this aspect of the circumstances has not been duly recognised, and our chief exhibition, possessing as it does the prestige and dignity of a national institution, has been open to all who shall pay a trifling entrance fee; good and bad, without selection, are accepted; without discrimination, all are hung and exhibited to an ignorant public who have no choice but to view the whole as representative of the best that present-day photo-

"WAITING AT THE LOCK."

[W. Wilcox.

pulse and taken the temperature of the photographic community, can mistake the signs of approaching change. This chord Mr. H. P. Robinson has already struck with a powerful hand in the *Photographic News* of August 19th, and he pleads for separate exhibitions for the art workers, where artists shall be judged by art experts. This no doubt is what is required, but such an exhibition would fail in attaining any real good if it be not

rigidly selective. When such a course is adopted, and the mere fact of being accepted becomes to be regarded in itself an honour and distinction, will the troublesome and long vexed question of medal awarding find of itself a clear solution.

But if all this prominence be given to art photography, we

"NEWHAVEN FISHWIVES."

Taken by Mr. F. W. Hindley in Fallowfield's "Miall" Hand Camera.

hear it said, what about the technology and science to which the artists owe their materials and processes?

We have said the foregoing, not with any desire to depreciate the importance of scientific enterprise and research, but from a desire to secure just recognition of the artistic possibilities of photography. There is no need to champion its scientific accomplishments, its wonderful mechanical progress, or its adaptation to commercial and industrial ends. All this is proverbial, and is so well recognised as to have absorbed attention to the neglect of its other interests.

Let the prejudice of the intelligent public, as regards artistic photography, be once shaken and the old ideas overthrown, and photography in incompetent hands will no longer be tolerated, but good photography will go forward and, judged fairly on its own merits, need fear nothing.

Then each photographer will be compelled to show real merit in all he does, or give up the camera, except as a plaything, and each photographic picture must exhibit some worth to justify its existence outside the privacy of its author's work-room.

There is hope in the near future, and a recognition and reward which may make it worth while devoting time and labour to an art which has too long stood without the threshold waiting admission.

York.—On 6th inst. the Secretary exhibited and explained the working of a shuttle hand-camera kindly sent by Messrs. Houghton and Son. The ingenuity and simplicity of the mechanism for changing the plates drew forth many admiring comments. Messrs. Beck had also sent a "Bynoe" printing frame for inspection. Several members gave their experience of the Paget Prize plates and Eastman's Solio paper distributed at the last meeting, the opinions expressed being very favourable. The Secretary had on view a large number of prints, the result of his season's work, comprising views of York and its minster, Scarborough, Forge Valley, Hayburn Wyke, Bridlington, Bolton Percy, etc. He had used Castle plates for most of the negatives, and the prints were on Eastman's Solio, Jacoby's collodion, and Ilford P.O.P. Messrs. Hick and Dickinson had some capital enlargements, and Messrs. Vincent and Bainbridge prints.

## To Arcadia with a Camera.

BY LIEUT. G. HARVEY.

THIRTY-SIX and a half miles from London Bridge (L. B. and S. C. Railway) lies Horsted Keynes, a place of singular beauty, and exceeding interest to the man of art—a veritable Arcadia, as yet quite unknown and unfrequented by the artist or photographer. As a matter of fact the natives eyed my camera with evident suspicion, doubtless taking it for an infernal machine, and myself for a dynamiter.

There are some of the most lovely spots imaginable in this neighbourhood, and I strongly advise all those who are in any way anxious to secure charming negatives to pay Horsted Keynes a visit. The village is two miles from the station down some pretty lanes (be sure to enquire the way from the station master), and after a walk of a mile or so, one approaches a fairish hill with some beautiful and picturesque old cottages on the left-hand of the summit; on the right, woodstacks. Expose a plate here. Reaching the village green, the eye is pleased with the charming prospect, and another plate may be advantageously exposed. Note the magnificent view on the left, with a glimpse here and there of shimmering water. Turn to the left, down a short but steep hill, and you will come to the church of St. Giles', a wonderful old structure. Give this three plates. (1) church and churchyard; (2) church and schoolhouse; (3) church, schoolhouse, and cottages. You will have to recede thirty paces or so for the latter.

Enquire for the following, and give each a plate:—

- (1) Rectory and grounds; (2) the park; (3) the lakes; (4) Mr. Hoadley's farm; the spinney and rabbit warren.

I could mention many other spots, but refrain, as weight of plates may be objected to. One could take two dozen plates with him, and then cry for more. Two more tips in conclusion. Firstly, on the right-hand side of the green you will find an inn at which you can get a good old-fashioned tea with everything fresh, at a trifle not worth mentioning—you will also get civility, and the landlady will darken

Miss Catherine Weed Barnes smiles on the operator, Mr. F. W. Hindley.

a room for you with pleasure. Take your folding ruby with you. I was treated with much courtesy, and the good hostess drove me back to the station in the evening, refusing my offer of payment. Show her this paper and your reception will be a royal one. Secondly, the sexton will prove an invaluable aid in any manner. He is most obliging and wants nothing for it. His cottage is the first on the left-hand side as you approach the church. One cannot mistake it, as there are only three there.

## Submarine Mining and Volunteer Submarine Miners.

MR. PAUL LANGE, of Liverpool, the well-known Norwegian and Icelandic traveller, has to a previous volume contributed specimens of his photographs of submarine explosions; and the following account, with illustrations, of his latest work in this direction will be of interest.

the command of Major A. H. Knight, have quite recently completed their fifth annual training. The corps was raised early in the year 1888 by Major Robert Montgomery, now the Honorary Lieutenant-Colonel Commandant of the division.

The officers set apart one afternoon during their training in order to explode some submarine mines and extemporised charges, for the purpose of demonstrating the utility of the submarine mine as a means of defence. In addition to Major-General Hall, commanding the North-Western District, and his staff from Chester, members of the Press, and many gentlemen, merchants, shipowners, bankers,

50 LB. CHARGE.

25 LB.  
CHARGE.

100 LB. CHARGE.

The "submarine mine" differs from the "torpedo," inasmuch as the former is stationary and defensive, while the latter is locomotive and offensive. The submarine mine is submerged and anchored in a given channel or estuary, and is so placed to impede the progress of a hostile vessel. The torpedo, on the contrary, is launched overboard and hurled against the enemy's ship. The former is in charge of the Royal Engineers, the latter under the charge of the Royal Navy.

A submarine mine is a metal case, pear-shaped, drum-shaped, or spherical in pattern, according to circumstances (the first-named is now almost obsolete), containing explosives, and fitted with an apparatus for bringing about an explosion at will. For purposes of defence it is laid in a channel through which an enemy's vessel may attempt to pass. It requires an electrical cable connection with the shore, and it is this cable which is a chief source of expense in submarine mining work. In the mine there is a fixed apparatus consisting practically of a short length of fine wire surrounded by a detonating composition. The cable connecting the mine with the electrical batteries on shore places the wire in circuit, the various parts being so proportioned that when a certain current is transmitted, the wire is sufficiently heated to detonate the surrounding composition and fire the mine.

Submarine miners are required to learn how to load a mine, place it in position, and work the whole apparatus generally for firing, so that the explosion can be effected at any moment by the officer in charge of the "Test Room" in the fort on shore.

The War Office authorities have paid our volunteer engineers the compliment of entrusting to a very large extent the defence of our commercial ports to volunteer submarine miners, whose officers cheerfully undertake the arduous but interesting duties connected with their work, and it is one of the conditions of their service that they attend the School of Military Engineering at Chatham, and prove before the instructors of submarine mining their knowledge and qualifications in the technical detail of this branch of the work of Royal Engineers.

There are now volunteer divisions of submarine miners on the Tay, the Tees, the Tyne, the Clyde, the Mersey, the Severn, the Forth, and Falmouth, each division being under the command of a major, and subject to the same conditions of service, the most prominent feature being the compulsory annual training of fifteen days.

The Mersey Volunteer Division, Submarine Miners, Royal Engineers, to give them their "Army List" designation, under

SS. "LORD HEATHFIELD."

underwriters, and those interested in shipping circles in Liverpool, were invited on board the *Lord Heathfield*, the steam miner on the Mersey station, to witness the demonstration.

Mr. Paul Lange, of Liverpool, was invited to be of the party, so that he might reproduce by photography the effect of the explosions.

His pictures have been very successful, and are much appreciated by the officers of the corps, as also by the commanding Royal Engineer, North-Western District, and by the Inspector of Submarine Mining Defences, War Office, Whitehall, both of whom have expressed their appreciation of Mr. Paul Lange's work.

## The "Frena" Hand-Camera.

MESSRS. R. AND J. BECK, of 68, Cornhill, London, E.C., have placed upon the market an extremely ingenious hand-camera for use with cut films.

FIG. 1.

The external appearance of the camera, which measures 8 by 6 by 4½ in., is shown in fig. 1, and it is neatly covered with black morocco leather. The camera is arranged for cut films, which are contained in

a box at the back of the camera. The films, which, by the bye, are Edwards's special instantaneous isochromatic flat films, can be bought in packets of twenty, price 2s. 6d. To fill the box, a dummy card is

FIG. 2.

FIG. 3.

first placed in the box, then the packet of films laid on top. The films are notched, as shown in fig. 2. Between each film is a piece of cardboard also notched, but alternately with the film; this card forms a protecting mask and prevents light from having access to

by means of the little pimples shown on the plate. The resetting of shutter does not uncap the lens, and it is set free by the little pin shown in the lower corner of the camera (fig. 5), whilst the pin level with the finder is used for time exposures.

Having fired off, to change the film it is only necessary to release the register spring and turn the handle, in the direction of the hands of a clock, nearly right round, as shown in fig. 6, and then back again, the exposed film being thus dropped into a well, and the new film being ready for exposure. The interior fitting of the camera and the movement of the box is also seen in fig. 7.

FIG. 6.

The camera is fitted with a well-sunk and properly adjusted finder. The focus of the lens is  $4\frac{1}{2}$  in.; aperture  $f/11$ , and the size of the picture 3 by  $3\frac{1}{4}$  in.

One special feature about the camera is that the box containing the films may be swung axially with the lens, and thus drunken

more than one film. On the top of the packet of films—and any number up to forty can be placed in the box—is placed a spring, and the box closed (fig. 4). The back of the camera being closed and the strap fastened up, we are ready for setting the shutter, which is an aluminium plate working in front of the lens, which is of special construction, working at fixed aperture and fixed focus of 13ft. To set the

FIG. 4.

FIG. 5.

shutter the cover plate of the lens is swung on one side and one or two turns of the milled head, as shown in fig. 5, sets the shutter, which works from  $\frac{1}{10}$  to  $\frac{1}{2}$  sec. and time, the varying speeds being obtained by contraction of the aperture of the moving plate

architecture be avoided. We present our readers with two blocks illustrative of the work done by this camera, and we have used it nearly every day for the last week, and performed the operation of changing without the slightest hitch. Speaking from our experience, the lens covers very sharply, and the camera is one which deserves the attention of every lanternist and enlarger. It is a triumph of ingenuity and simplicity, and we cannot see how it is possible to make a miss shot with it.

FIG. 7.

#### Tooting Camera Club.

—On the 8th inst.—lantern night—slides of English, Scottish, and Continental scenery were shown by means of the President's new limelight lantern to a large number of members and friends. By the kindness of the Paget Prize Plate Co., sample packets of their plates were distributed to the members for trial; a framed enlargement of instantaneous pictures taken on their plates was also sent for the club room.

## How to Make a Set of Photographic Apparatus.

By H. J.

(Continued from page 175.)

### CHAPTER VI.

#### THE HAND-CAMERA.

To possess a hand-camera—or, as it is often called, a detective camera, is, I think, the ambition of every amateur; but, unfortunately, it is an ambition not always realised, for though they can be bought at any price from five shillings upwards, too many of the cheaper ones are worse than useless and cause the user to throw them aside in disgust, and many of the more expensive ones are complicated affairs which are apt to go wrong at the least provocation, so that it is extremely difficult for an amateur to choose the best for his purpose. It has often been stated by many of the best known workers, that what is needed in a hand-camera is a sure and certain method of changing plates; arrangements so that any number can be carried, and not to be confined to a dozen or so; finders for both vertical and horizontal way of plate, adjustable focus, rising front, and swing back; and also to be adapted to use on stand if required, and focussed in the usual way on ground-glass.

FIG. 47.

All these necessary arrangements are embodied in the camera which is the subject of this chapter, and it will necessarily follow that as viewed on paper it looks rather complicated; but if my directions are followed out to the letter it will be found to come quite easy, and all seeming complications will vanish as we go along, and as, in an instrument of this description, the time occupied in making is the largest item in the cost, all who make this one will possess as good a camera as can be bought, which will not cost them above one sixth what it would have done if purchased complete, and will have the additional satisfaction of being able to show it as their own work.

Before commencing the making of the camera, perhaps it will be as well if I describe the different drawings, and the method of working the parts, so as to make myself better understood afterwards.

Fig. 47 is a longitudinal section of camera complete. The plates are contained in a plate-box, A, which is divided into divisions the right thickness for one plate to slide in easily. I have only shown four divisions, for the sake of clearness. Fig. 51 is a sketch of the plate-box itself, with the lid partly drawn. It will be seen that on the top of the box are two pieces marked B B, with a groove in them; these also show in fig. 48 and one of them in fig. 47, being marked B in each place. In fig. 48 is shown the piece which fits in the groove marked C, and this piece again is screwed to the piece D, figs. 47 and 48. This piece is of the same size as the plate-box is outside. To this last piece D are fixed four tapes, one at each corner, E E, figs. 47 and 48. These tapes pass up

over the small brass rollers F, and are connected with the block G. This block is connected with the screw H, the head of which is on front of camera, and on turning which the plate-box will be raised or lowered as is required.

Now as the plate-box only holds a dozen plates, it is necessary that we should have some arrangements so that

FIG. 48.

when they are exposed they can be removed, and unexposed plates inserted in their place; this is effected by means of the sliding lid which, on looking at fig. 51, will be seen to open downwards and also to have a piece fixed on the bottom (I). This piece has two small holes in it as shown, and in the partition of camera K, fig. 47, are inserted two screws, projecting through the partition about an eighth of an inch.

Now on the plate-box being placed in camera, the holes in I will be filled by the screws in K, and on the box being raised by means of the screw H, the lid will be held still and the box will be opened; and after all the plates are exposed, and the box lowered the lid will close again, and the whole can be removed and another box full substituted.

We must now look at fig. 47 again in order to show how the plates are to be exposed. This is done by means of the swinging frame L, fig. 47, which swings back as shown, so as to be opposite the slot in K, and the plate opposite the slot on the other side (in the plate-box) slides into it; it is then swung into a vertical position as shown by dotted lines, the slip M forming a stop for the frame.

The effect of a swing back is given by making M to slide along the bottom of camera either way by means of a lever, which I shall describe hereafter.

After the plate is exposed it is returned to its original place in plate-box, and the screw turned so as to bring the next one opposite the slot. A slip of paper with numbers on it is pasted on G, which can be seen through slot N, fig. 50, in top of camera, so as to keep a record of the plates exposed.

FIG. 49.

The lens is fixed as shown at O, and is focussed by means of a lever at the side, which I shall explain in the proper place, and is also made to rise and fall by means of racks and pinion. The front opens for adjustment of stops of lens, and the back for the insertion and removal of plate-boxes.

I will now show how the camera can be used on a tripod, with ground-glass for focussing. The glass can always be carried in the camera underneath the plate-box, the latter being made so as to allow room for it, or better still, a piece

FIG. 50.

can always be placed in bottom groove of plate-box; the latter must then be drawn up so that the glass will slide into exposing frame, which being turned up in its place will show the view on it at once, no focussing cloth

being required. When the correct focus is obtained, the ground glass must be replaced and the box lowered to the next groove, when the exposure can be made in the usual way, either with shutter or time.

Having got through this rather long introduction, I will now get on with the instructions for making, and I must again ask all to follow the directions carefully, making each separate part as stated here, as if done otherwise some parts will be found not to fit in their proper places, and

this will of course cause failure. The first part to make is the plate-box, fig. 51; for this, prepare a piece of mahogany an eighth of an inch thick (the three-ply fret wood is very good for this), 15 in. long and  $3\frac{1}{2}$  in. wide, and run a sixteenth of an inch groove on one side, an eighth of an inch from the edge, now cut off two pieces  $2\frac{1}{4}$  in. long (cutting them square) and the remaining length cut in the middle. In these two longer pieces cut a trench at each end, leaving a space of  $4\frac{3}{8}$  in. between the trenches, which must be the right size to take the ends of the two short pieces; now

FIG. 51.

plane off the edge where the groove is, in one long piece, into the inside of groove, and then fix the short pieces into the trenches with glue and very fine screws, keeping the grooves together so that the lid will slide in. When the glue is set, plane off the back level all round (the back is the part farthest away from the grooves), and glue and screw a piece of the same kind of wood on, using plenty of screws, and keeping the box exactly square. While the glue is setting prepare some pieces for the divisions; these can be as thin as you like, and if you care to go to the expense, ebonite is very good for them, though wood will do. They must be made  $4\frac{3}{8}$  in. long by  $3\frac{1}{4}$  in. wide, as this size will just fill the box lengthwise, and will reach nearly to the grooves in width. We shall also want some pieces to go between the divisions; these must be a sixteenth of an inch thick, and the same size the other way as the thickest negative you can find is thick, and must be cut off in lengths of  $3\frac{1}{4}$  in.

Now take the plate-box, and laying it on its bottom with the open side towards you, glue one of the small strips in each bottom corner—see fig. 53—then place a division on the two pieces, then two more strips and another division, until the box is full. They can all be put in at one time, rubbing the strips well into the corners; and do not leave any glue in the grooves, or it will interfere with the plates sliding in and out. When the glue is set, the box can be cleaned off outside, and the lid made; this would also be made of ebonite by preference, and the strip I glued and screwed on it. Make it a good fit, so that it will slide easily in and out, but not so loose as to drop out by itself. Now make the two strips B B, fig. 51, and screw them on level with outside of box, at the top as shown, and the plate box can be considered finished.

It may be thought that grooving would do for the box, and thus do away with the necessity for divisions; but my reason for using the latter is, if by any chance a ray of light enters, the whole lot of plates would be affected in the former case, but in the latter it would affect one only. Of course, if the plates were in sheaths it would be different; but I prefer to do without sheaths, both on the score of cost and convenience, not to say anything about extra weight.

FIG. 52.

The camera itself can now be made, and no better wood will be found than mahogany, or if it is to be covered with leather or cloth, then American white wood is very suitable;  $\frac{1}{4}$  in. will be thick enough, as lightness is a necessary condition. The full size for a lens of five-inch focus will be 11 in. long, by 5 in. deep, outside. The width of course is given by the plate-box, which was my reason for making that first. The two sides and top of camera are each in one piece, but the bottom is made up of three pieces, as shown in fig. 48. The bottom had better be prepared first so that the whole can be set out together; therefore take a piece of wood about 12 in. long and 6 in. wide, and cut a piece an inch

wide off each edge, joint these pieces on again and match them together with tongue and groove joints as shown at P, fig. 48; then cut the middle piece asunder  $4\frac{1}{2}$  in. from one end, and joint the two ends together with tongue and groove in the same way. The two outside narrow pieces can then be glued on to the longer of the two middle pieces, leaving the shorter (the  $4\frac{1}{2}$  in. piece) loose, to form a sliding door in the bottom; this is for a purpose to be explained later on. The two sides can now be taken to about 5 in. in width (it does not matter to a trifle, so that they are both just alike), and a groove run with the match plane along the sides at each edge, and the top and bottom must also be taken to the proper width, and a tongue run on the edges, as shown in fig. 48; then put the four pieces together temporarily and try the plate-box; if it just goes in easily it will do, but if there is more than a sixteenth of an inch side-play, take another shaving or two off the top and bottom, as the closer it works the better, so as it is not too tight.

The sides and top and bottom must now be squared off to 11 in. long (or longer or shorter according to the focus of your lens), and rabbets cut all round inside to take the ends, as shown at each corner in fig. 47. In marking the bottom off to the length, the joint of sliding lid must be 4 in. from one end, letting the distance from the other end come as it will; this is important, as will be seen later on. A trench can now be cut in the sides and also in top and bottom for the division K. That in the bottom will be formed where the end of lid comes, the joint forming one side of trench, and the trench itself cut on the extreme end of lid; and the others, of course, will be cut at the same distance from the end, so that when put together the trench will continue all round.

The division itself can be made next, and must be built up of three pieces in the same way as the bottom, as it is necessary that the middle part *below the slot* be made to slide downwards, when the lid in bottom is opened slightly, otherwise the image on ground-glass could not be seen when focussing. As this part is made exactly as the bottom, I have no need to go over the same ground again, so I will only mention that the slot through which the plates pass into swinging frame must be exactly in the centre, and runs from side to side, *not* from top to bottom. The width, or perhaps I should say the length of slot must be  $4\frac{1}{4}$  in. full, so as to leave room for plate to pass easily, and the same distance across as the divisions are between in plate-box. The edges of slot can also be rounded off slightly, so that they cannot scratch the film of plate. Now take the two sides again and run a groove in each along near the top edge, leaving about a quarter of an inch clear between them and those already run; but do not run them through from end to end, only from front end to the trench in which division K is to fit; these grooves are for the block G to slide in. The camera can now be put together for good, using both glue and screws, and placing K in its place, as it cannot be put in after. But before putting it in cut out two small slots at the top for the tapes to pass through, and as you are putting the case together, the rollers over which the tapes pass must be placed in their respective places; these are lengths of brass wire with a hole through the centre, and nothing is better for them to run on than a common knitting needle cut to the right length to enter each side about an eighth of an inch, and passing quite through the rollers. They should be placed as near the top as possible, so that there is room for the tapes to work without rubbing.

The block G must be made next. The size will be such as to slide in the grooves mentioned above, and about three inches wide, and the thickness will be the same as the brass

nut of screw H, which must be fixed in front side of it, and a hole made through the block for the screw to pass through. The four tapes (which will do of any ordinary good tape) can now be fixed to the opposite side of block to where the nut of screw is fixed. They will be fixed, two at each end, one top of the other; then pass them through the slots in K, and over the rollers, the bottom tapes over the roller close to K, and continuing the other two on, and passing them over the other roller. Then slide G in its grooves, as far back towards K as the length of screw will allow it to go, then draw out lid in bottom of camera, and turning the whole over, fix ends of tapes between C and D (fig. 47) by screwing the two pieces together; this will hold them firmly, and they can be easily adjusted at any time. The plate-box should now be put in its place, and the block G pulled to and fro to ascertain if the tapes are the proper length; if so, they should raise the box smoothly and easily from top to bottom of camera, without any rubbing or friction, and if they do not it is most likely owing to one or more of the tapes being slightly longer or shorter than the others, which had better be put right at once, as the box must hang level or the plates will not enter the slot in K. I will now postpone the finishing of the camera to the next chapter, but I give below the list of fittings required, so that they may be obtained before commencing work, which, as I have said before, is by far the better way.

	s.	d.
Milled head screw H .. .. .	3	0
* 2 pair hinges (for front and back lids) ..	0	9
2 brass rollers for tapes .. .. .	1	0
* Fittings complete for swinging frame L ..	1	0
* Racks and pinion for rising front .. ..	3	3
* 2 brass levers for focussing and swing back ..	1	0
* Spring and eye for shutter .. .. .	0	6
* Spring catch for front lid, and lock for back lid .. .. .	2	0
Divisions and lid for plate-box, ebonite, $\frac{1}{16}$ in. thick, each .. .. .	0	1 $\frac{1}{2}$
* Plates, hinge and turn-button, Z, a, b, and l, fig. 49 .. .. .	1	0

Those marked thus \* have to be described in chapter VII.

#### DESCRIPTION OF FIGURES (CHAP. VI.)

- Fig. 47. Longitudinal section of camera, complete.

 „ 51. Plate-box, showing lid partly drawn.  
 „ 52. Detail showing method of opening lid when in camera.

#### DESCRIPTION OF REFERENCE LETTERS.

- A. Plate-box in position.  
 B. Grooved strips to connect plate-box with tapes.  
 C. Centre-piece fitting between B B.  
 D. Connection between tapes and C.  
 E. Tapes for raising and lowering A.  
 F. Rollers over which tapes pass.  
 G. Block connected with screw.  
 H. Milled-head screw to work plate-box.  
 I. Strip to open lid of plate-box.  
 K. Division of camera.  
 L. Exposing frame.  
 M. Stop for exposing frame, also forming swing back.  
 N. Slot in top of camera to register plates.  
 O. Strengthening piece to front.  
 P. Stop for exposing chamber when in horizontal position.  
 P' Method of forming sliding-door in bottom of camera.  
 R. Bearing of exposing chamber.  
 S. Handle of exposing chamber outside of camera.  
 T. Levers working swing back, and sliding front.  
 U. Guides for rising and falling front.  
 W. Pieces to carry shutter.  
 X. Frame of shutter.

- Z. Sliding plate carrying arrangement for setting and releasing shutter.  
 a. Plates for Z to slide in.  
 b. Trigger to release shutter.  
 1. Hinge for setting shutter.  
 2. Method of hinging shutter when lens is fitted with movable stops.

(To be continued.)

## Some Notes on Enamelling Gelatino-chloride Prints.

BY W. PITCAIRN CRAIG.

NEARLY all photographic papers are capable, more or less, of being finished with a very brilliant surface by the comparatively simple process of drying in optical contact with glass; but gelatino-chloride papers—Obenetter, Aristotype, Solio P.O.P., etc.—lend themselves *par excellence* to this method of finishing.

The failures which many amateurs experience being due principally to want of patience and want of strict attention to details, I will, as shortly as possible, describe the whole process, from the preparation of the glass to the final mounting—not deeming the minutest details unworthy of notice.

Well, first let us prepare the glass. Most of us have, unhappily, at least a few spoiled negatives which, if we can remove the old films, will serve our purpose excellently. This is done by soaking the negatives for a short time in a mixture of one part of hydrochloric or sulphuric acid to twenty parts of water; the film will then, if it is not varnished, peel off at once; but if varnished, its removal is more troublesome, as it has first to be soaked in methylated spirit of wine, to remove the varnish, on which the acid has little or no effect. Well, the film having come off satisfactorily, the glass should be first thoroughly washed in hot water, a hard nail-brush being used to remove any remains of the film; then rinsed through cold water, after which it must be carefully dried and polished. A little powdered French chalk should now be dusted over it and gently rubbed off with a soft linen cloth till all traces of the chalk have disappeared. It is sometimes recommended to first treat the glass with a solution of benzine and beeswax, but this seems to me quite unnecessary, besides which, it is very difficult to prevent the benzine leaving streaks on the finished print which by no means enhance its beauty.

Now, the glass being ready, the print is taken from the water and laid face downwards on the prepared side of the plate; a piece of sheet rubber, rather larger than the print, is laid on the back, and the squeegee passed firmly but gently over it, expelling all air-bubbles and moisture, being careful not to crease the print, which will then adhere firmly to the glass. If it is not wished to mount the enamelled print, there is no more to be done beyond allowing it to dry; but if it is to be subsequently mounted, it will be necessary to paste, on the back, while the print is still on the glass and wet, a piece of waterproof backing paper—such as that sold by Wheeler and others—as, if it were pasted directly on to the mount when dry, the moisture would penetrate the paper and ruin the glazed surface. A very good way of preparing the starch with which to execute this preliminary mounting is this:—“Break” one part of Colman’s hot-water starch with two parts of cold water; when all lumps have disappeared, add other four parts of water and stir well, place in a clean pan and heat, stirring continuously, till it thickens and turns blue. A small quantity of this, avoiding the skin, is applied, when cool, to the back of the print with the ball of the middle finger, by which it is possible more thoroughly to remove lumps and superfluous starch than with a brush. Place a piece of backing paper on the print and carefully squeegee down, expressing as much of the starch as possible. The print, attached to the glass, is then laid apart in a warm room to dry, an operation which occupies at least four hours; in a dry, warm atmosphere one is pretty safe in stripping the print in about six hours. To do this, as the starch will have attached the edge of the waterproof paper to the glass, it will be necessary to cut with a sharp-pointed knife and a straight-edge round the print, taking off the superfluous backing paper and as narrow a strip as possible of the print, being careful to cut right through to the glass.

On raising one of the corners, the print will now peel off with as brilliant a surface as anyone could desire, and, it must be remembered, one that is very easily injured. Now we have yet to attach it to the mount proper; the usual way to do this is to apply starch as for an ordinary print, but I have found, after a good deal of experience, that this has always an injurious effect on the polished surface, and I consider the following method much better. Run round the edge of the backing paper a line about one-eighth of an inch wide of Le Page's liquid glue, using as small a quantity as possible and being careful that no glue reaches the polished surface; unless the bottle be newly opened, it should be placed in hot water to thin the glue, thus allowing a small quantity to be used. Place the print on the mount and press into contact for a few seconds with a piece of clean glass.

Care should be exercised in the choice of mounts for enamelled photographs. Plate-sunk mounts are suitable, but perhaps the best are cut-out mounts, with which, of course, the glue is applied to the mount, not to the print. Although backing paper is not absolutely necessary when using cut-out mounts, yet it is advisable to use it, as it gives strength and rigidity to the photograph.

This method of finishing will often make a poor, flat-looking print quite presentable, and will sometimes bring out details not before visible and give a general sharpness to even a good photograph.

In conclusion, let it be remembered that prints may be enamelled over and over again; and if, after being stripped from the glass, the surface be found to be unsatisfactory, the operator should not hesitate to soak it in cold water—hot would bring off the film—till the backing paper comes off, and begin anew, keeping in mind the old adage, "What is worth doing at all is worth doing well."

## Apparatus.

### THE PHOTO RUBBER STAMP.

MR. WM. TYLAR, of 57, High Street, Aston, Birmingham, has introduced a very striking novelty, namely, an indiarubber stamp which can be made from any print sent him. This will be found very useful in business as well as being a pleasing novelty, as the impression will take on any smooth surface, such as silk, leather, etc., in any colour.

### WEBBER'S SENSITISED PAPER.

Mr. William Webber, of The Laurels, Kennington Avenue, Bristol, has sent us a sample of his ready-sensitised paper, which we have found to give rich brilliant prints, and tone easily with freedom from blisters.

### THE "N. AND G." ALUMINIUM BLIND SHUTTER.

Messrs. Newman and Guardia, of 71, Farringdon Road, E.C., have introduced a new blind shutter, the principal parts of which are constructed of aluminium. It is fitted with Newman's patent automatic regulator, and it gives speeds varying from one second to one-fiftieth of a second, and time exposures. It can be fitted at the back, on the hood, or between the lenses, and has an air cushion to prevent vibration. One size only of 1½ in. diameter is ready at present, but other sizes will shortly be ready. The price is 45s.

## Societies' Meetings.

**Ashton.**—On the 3rd inst. was held the last outing of the season. This time the rendezvous was Chester, and the outing was most enjoyable. The members of the society and their friends, to the number of about forty, including several ladies, assembled at Park Parade station at 6.45 on Saturday morning, and five minutes later were whirling away on the new M. S. and L. route *via* Central Station, Manchester, to the ancient city on the banks of the Dee. The party included Mr. G. H. Dean (secretary), Mr. C. E. Redfern, Mr. T. Glazebrook, Mr. R. T. Marsland, Mr. W. C. Brown, Mr. T. Cheyne, Mr. Percival, Mr. R. Matthews, Mr. J. Hutchison, Mr. W. Leigh, and Mr. W. Chadwick. Chester was reached about ten minutes past nine, and at the station the trippers were met by their leader, Dr. Hamilton, who had proceeded there on the previous day to make arrangements for the day's outing. The greater portion of the contingent wended their way to the famous Cathedral, where special permission had been obtained to photograph the interior. The early part of the forenoon was whiled away pleasantly until 12 o'clock, at which time all assembled on the river landing stage, awaiting the arrival of the steam launch, which Dr. Hamilton had specially chartered. Presently a trim little boat, "The Ontario," steamed up, and all being aboard away they went for a trip up the river. The first calling place was Eccleston Ferry, where Mr. Joseph Hutchison took a picture of the group on board, the plate being a 12in. by 10in. A "shot" was also taken of the party by Mr. Matthews. Then the party disembarked, and a pleasant hour was spent in photographing the beautiful river scenes which are to be found here in abundance. All being aboard again, a quick run brought them to Eaton Hall, the seat of the Duke of Westminster, where another halt was made, and the party landed in the private grounds. Special permission to do this had been obtained by Dr. Hamilton, and the privilege afforded the trippers a rare pleasure. For three hours they were seen roaming about the well-laid-out grounds. Some capital pictures were taken here. At five o'clock the launch again steamed off with all on deck, and by six Chester was reached. Home was reached about 10.30. The weather had been moderately fine during the day, the slight showers which descended in no way inconvenienced the party, and the outing was a thoroughly enjoyable one.

**Burslem.**—The first meeting of the winter session was held on 6th inst., Mr. E. B. Wain (President) in the chair. Large attendance of members, one new one being elected. A large number of prints from negatives taken during the last two months by members were exhibited and criticised by those present. Mr. F. C. Powell gave a very interesting paper on "Development," which was followed with considerable interest by those present. The reader thoroughly and concisely explained the use and composition of a developer, and gave a number of examples of various combinations, also touching upon some of the newer substances which have been introduced lately. The paper concluded with a number of useful hints on intensification, reduction, retouching, and varnishing of negatives. At the conclusion a hearty vote of thanks was passed to Mr. Powell. The society is in a more flourishing condition than at any previous period of its existence, the members generally displaying the utmost interest in its welfare, and in spite of the adverse criticisms industriously circulated by the so-called Potteries correspondent of a monthly contemporary, who evidently knows nothing of its working, the society is in anything but a languid state, unless a constantly increasing membership roll indicates that it is slowly fading out of existence.

**Crewe.**—A party of members and friends enjoyed a very pleasant and interesting outing to Cholmondeley Castle by waggonette on 10th inst. The weather all the week had been very dull and wet, anything but promising, yet it changed and proved a very fine sunlight summer day, just right for photography—light good, and foliage perfectly still. Through the kindness of Mrs. Gartside, the lady and family in residence, permission was given to freely ramble about the park, grounds, and gardens. On arriving at the Lodge-gate, the small army of cameraists and friends walked through the park, enjoying the fine sights of stately trees, herds of deers, swans, and wild ducks on the lake, and on to the very fine Castle of Cholmondeley, elevated on the hill, and beautifully surrounded by trees, walks, and charming pleasure grounds and water fountains. It was their extreme pleasure and delight to both see and enjoy the lovely paradise of trees, ferns, and walks finely laid out for beauty and taste. Special thanks are due for the privilege and boon, so richly appreciated by the Crewe friends, to Mrs. Gartside, and to Mr. Talbot Wilson for obtaining the request. All found ample scope for the camera, and doubtless many very fine views would be taken. After a good substantial tea provided by Mr. Dodd, postmaster at Cholmondeley, and a gentle walk round, the party returned home, having enjoyed a thoroughly good day.

**Croydon.**—A general meeting of the Photographic section of the Micro. and Nat. Hist. Club was held on the 9th inst., Mr. Carter in the

chair. In addressing the meeting, Mr. Carter said they were brought together that evening to discuss and receive the opinions and ideas from the members as to the arranging of the coming winter session. Mr. E. Lovett, the President of the club, who was present, but unable to take the chair owing to other business calling him away, intimated to the members that the Institution Committee had made them an offer of their committee-room, to be converted into a dark-room and meeting-room, in the place of the dark-room they now had, and which could not be used on account of being so damp. The idea was well received by those present, and Mr. Goode proposed, and Mr. Waller seconded, "That it was the opinion of the photographic section of the club that it would be a great boon if the committee-room could be hired for the purpose of a dark-room, to be always available for the use of members." The chairman then said that that proposition would be placed before the general committee of the club on Wednesday next to receive their consideration. The chairman then called attention to a new question box which the club now had, and hoped the members would avail themselves of it. Suggestions were then received from the members present for the coming winter meetings, and will be considered and arranged in due course by the photo sub-committee.

**Derby.**—The above society had one of their very enjoyable outings on the 10th inst., going to Melbourne, which, with its quaint old church and picturesque lake, offered good opportunities for camera work. Through the courtesy of Mr. Fane, his extensive grounds, laid out in Dutch style, with ancient yew tree hedges, were opened to the society, the light being excellent, some good views were obtained, and the return journey was made in the early evening. The society have as a guest Miss Catherine Weed Barnes, of New York, who has also been entertained by Messrs. Keene and Scotton, who accompanied her to Haddon Hall, Matlock Bath, and Wingfield Manor, and a number of exposures were made. The excursions have been much enjoyed, and it is to be regretted that they are so nearly at an end.

**Devonport** (R.N.E. College Photo Club).—At a recent meeting of the members the following were re-elected:—President, W. S. Hill, R.N.; Committee, H. M. Wall, R.N., J. S. Constable, R.N., F. J. Charlton, R.N., and W. B. Hall, R.N.; Hon. Sec. and Treasurer, G. W. Leslie, R.N.

**East London**—The members met on the 7th inst. at the "London Apprentice." The business done was the discussion of a light supper and presentation of a half-plate wide-angle R. R. lens, suitably inscribed, to the energetic Hon. Secretary. The President, in making the presentation, congratulated Mr. Wilkinson on the efficient and courteous manner in which he had carried out his arduous duties. Mr. C. Tylee (Vice-President) fully endorsed what had been said by the President, and proceeded to heap further encomiums on the head of the Hon. Secretary. The health of the Hon. Secretary was then drunk with musical honours. Mr. Wilkinson in his reply thanked the members for their gift, which was most acceptable, inasmuch as it completed an otherwise incomplete half-plate outfit.

**Hackney.**—On the 6th inst., Mr. A. Barker in the chair, several members complained of the inaccurate manner in which meetings had been reported during the absence of the Hon. Sec., and in consequence the minutes of the preceding meeting were ordered to be rewritten. Mr. S. J. Beckett, of 6, The Grove, Hackney, was nominated for membership, proposed by Mr. Sodeau, and seconded by Mr. Hensler. Donations:—A cabinet portrait of Mr. Harverson, taken by himself for the album, and six blue glasses for testing dark-room lights from Mr. Sodeau. Work was shown by Messrs. S. Beckett, Harverson, Hudson, Nunn, and Sodeau. Mr. Nunn showed the result of testing a ruby lamp with an Ilford red-label plate; it was pronounced safe. Mr. Hudson showed a negative and lantern slide developed with amidol; he was much pleased with this new developer, and had developed eight plates in succession with one portion of developer. Mr. Beckett did not think that amidol would be very suitable in cases of over-exposure, but thought that it would prove excellent in cases of under-exposure and for lantern slides, etc. Mr. Hudson had found that some sulphite of soda which had been exposed to air did not completely dissolve in water, and did not prevent stain to the same degree as the fresh substance. Mr. Sodeau said that this was due to its having been oxidised to sulphate. Mr. Gosling asked whether sulphite of soda and metabisulphite of potash would keep in solution. It was stated that they would keep if air be excluded; solutions of sulphite of soda should be acidified. A member had developed a lantern plate with pyro and sulphite of soda only; it was remarked that sulphite of soda is alkaline. A member asked whether pyro-soda could be used for developing more than once; several members did so, but others thought that it was not advisable, especially in case of under-exposure. Mr. Capell asked what effect citrate of soda had in developing; it was stated that it was very useful in cases of over-exposure, as it allowed the negative to gain in density while preventing detail from coming out.

**Lewes.**—The annual meeting was held on 6th inst., under the

presidency of Mr. Tunks. Mr. Bedford, the Honorary Secretary, read the following report:—"There are at present forty members on the books, nine new ones have been elected during the year, and seven have resigned. Ten ordinary meetings have been held during the year, and have been fairly well attended. The excursions have been so badly attended that it is contemplated to discontinue them unless they receive better support. The Treasurer's report shows a balance in hand of £1 3s. 5d. It is with much regret that the Council have to mention the loss the society has suffered by the resignation of Mr. J. G. Braden, who has held the position of President since the formation of the society, he having left the town; also their regret at the loss of so energetic and a useful member as Mr. Percy Morris, who has likewise left the town, but they are pleased to know that both these gentlemen will continue as members of the society. Finally, the Council wish to thank the Press, local and otherwise, for their notices of meetings, excursions, and for kindly sending copies of their papers." The report was adopted, and on the motion of Mr. Wightman, seconded by Mr. Wells, Mr. Tunks was unanimously elected President. Mr. Wightman was appointed Vice-President. Mr. Constable was elected Honorary Secretary in the place of Mr. Bedford, who resigned the office, having found it impossible to give the amount of time required to carry out the duties, and Messrs. Funnell, Young, Carpenter, Bedford, and Curtis were elected on the Council. A vote of thanks was passed to the Paget Prize Plate Company for a framed enlargement of snap-shot pictures taken on their plates, and for the sample packets of plates sent by them, which were distributed to the members present for trial and report at a subsequent meeting. A new style of printing frame, the Bynoe, sent by R. and J. Beck was shown and generally considered to be a good thing. All communications for the society should now be addressed to the Secretary, Mr. H. B. Constable, 5, East Street, Lewes.

**London and Provincial.**—On 7th inst., Mr. Haddon in the chair. Mr. Haddon presented the Association with a copy of Burgess' "Argentic Gelatino Bromide Workers' Guide," one of the earliest manuals on dry-plate working, published by Morgan and Kidd. Mr. C. Goodwin Norton showed his registering templates, and a new device he had introduced for testing the flatness of field of lantern objectives. Mr. Parfitt showed Newman and Guardia's aluminium blind shutter and changing box. The following questions from the question-box were then answered:—How is the proper position of the stop in single lenses ascertained? Mr. Debenham said it was almost impossible to say. Grubb had made his stop adjustable so that it could be used to flatten the field if required by moving further out. Mr. Haddon suggested that it had been recommended to place it one-fifth to one-seventh of the equivalent focus in front. The second question was, What is the best method of treating developed plates when travelling, so that fixing may be postponed until at home? Mr. Haddon suggested well washing, but Mr. Debenham said all plates would not stand this. The general opinion was that if development could be effected, fixing could be done. A desultory discussion then ensued upon reversal, led off by Mr. Teape, but the subject was finally deferred to a future meeting.

**North London.**—On the 6th inst., Rev. E. Healy in the chair. This meeting, the first after the summer vacation, was devoted to reports of holiday work, and a good number of specimens of hand-camera work as well as of larger sizes occupied the attention of the members. It was noticeable that a considerable proportion had been taken on the Ilford and other Isochromatic plates, the results fairly showing the advantages of the colour correction. Almost without exception, the prints were on Ilford or Eastman printing-cut paper, toned under various conditions of bath, but in all cases with satisfactory results. Messrs. Beck's "Bynoe" printing-frame was shown, and attracted a good deal of interest, and the new developer "Amidol" was mentioned as to be reported on very shortly. Next meeting, September 20th, when a practice demonstration of retouching will be given by Mr. Redmond Barrett.

**North Middlesex.**—On the 12th inst., Mr. H. Smith in the chair, thirty-five members and a number of visitors were present. Mr. Beadle addressed the society on "Lantern-slide Making." He showed a frame for the purpose of printing by contact from any part of a half-plate negative made from a whole-plate printing frame. The ordinary back was removed and two thin boards substituted, the inner sides were covered with a soft material, and a square hole  $3\frac{1}{4}$  by  $3\frac{1}{4}$  cut in the centre of each. The negative was sandwiched between them, leaving the selected part visible through the opening, the whole arrangement being clamped together with the pressure springs. The lantern plate was dropped into the opening over the negative and secured in place by a lid fastened with one pressure spring. Mr. Beadle referred to the various lantern plates on the market, their peculiarities, and the tones to be obtained on them. He had long wished for a print-out plate, and had tried with success the following formula which he had recently seen:—(No. 1) Silver nitrate,  $\frac{1}{2}$  oz.; citric acid, 60 gr.; water, 1 oz. (No. 2) Nelson's No. 1 gelatine,  $\frac{3}{4}$  oz.; water, 6 oz. (No. 3) Alum

20 gr.; Rochelle salts, 20 gr.; ammonium chloride, 10 gr.; water, 1 oz. No. 2 was gently warmed and No. 3 added; No. 1 was then added drop by drop with constant stirring, heated up to 150 degrees, and filtered through two thicknesses of muslin, and the plates coated by pouring a pool in the centre and flowing all over. The only trouble he had met with was that it remained slightly tacky and would stain unvarnished negatives. Lantern-slides, large transparencies, and opal plates produced by this method were passed round for examination. The colours obtained by toning with the borax and cyanide baths were very fine, and though the plates had been repeatedly removed during printing for examination, no signs of doubled images were visible, as in replacing the plate care was taken to bring it into close contact with the same side and end of the printing frame. The lecturer then dealt with the minutiae of exposure, development, and toning of slides made by gaslight, and ended by making one or two slides of great beauty. A hearty vote of thanks was accorded to Mr. Beadle for the seasonable lecture he had given. The competition of views taken at Welwyn and Hadley was held, Mr. Allpress being declared the winner. The next meeting will be held on Monday, the 26th inst., Mr. Mummery in the chair, when Mr. E. J. Wall will lecture on the "Life of a Dry Plate." Visitors welcome.

**Richmond.**—On 9th inst., the President in the chair. Referring to the soda developer mentioned in the minutes, the Chairman remarked that for some kinds of plates the amount of soda should be halved. For time exposures it was advisable to begin with even less than that amount. Mr. Faulkner inquired which was the best method: To obtain density first and detail after, as he had seen lately recommended, or *vice versa*. He preferred getting the detail first of all; with Rodinal he had been unable to obtain vigorous negatives. Mr. Ramsay had had no trouble on that score. Mr. Ennis could get better density with pyro-soda than with Rodinal. Mr. Davis wished to know why in a recent article carbonate of soda was recommended as the alkali for hydroquinone, instead of the usual hydrate. Mr. Faulkner said that development being slower a finer grain and a better negative would be the result. The discussion having turned on fixing, Mr. Cembrano expressed the belief that fading of silver prints was often due to insufficient fixation. For negative work a dirty hypo bath was often the cause of stained or yellow negatives. Mr. J. D. Gibson said that climatic conditions also affected the permanency of albumen prints. Photographs which he had made in Madras, where the climate was dry and hot, had faded, while others done at the same time and under same conditions which he had sent to England had stood the test of time well. His experience of the climate in Ceylon, which was damp and hot, was that it also caused prints to fade. He added that want of permanency was due as much to unsuitable mounts and mountants as to insufficient washing out of the hypo. A member having asked whether prints on gelatino-chloride paper required as much washing as albumen prints, Mr. Ardaseer replied that the former required more, the paper being thicker and the hypo penetrating more into the gelatine. The discussion fixed for the evening on "Improving Faulty Negatives" was opened by the Chairman, who said that there were a number of ways of improving faulty negatives, but that whenever possible he recommended taking another negative. Covering the back of the plate with collodion, containing some aniline dye, such as aurine, was an excellent plan; those parts covering the over-dense spots of the negative could be scraped away. Mineral or tissue paper were also often used in a similar manner. By means of a stump and blacklead used on them, the light could be retarded on some parts of the plate. Sometimes a negative could be greatly improved, especially if a very flat and thin one, by making a transparency from it, and from this a negative. By suitable exposure and development the contrast could be very much increased. Intensifying the negative was often resorted to by some workers, while others preferred getting great density by development, and then using a reducing agent. For platinotype Mr. Willis had found that by printing under signal-green glass the quality of the resulting print was much altered. It was eminently suitable for hard negatives, as printing under this glass gave much softer images. He (the Chairman) had obtained a piece of signal-green glass, but the colour appeared to him to be a peacock blue by daylight. Mr. Ardaseer said that was so, but by gas or oil light the colour would show as green. If examined in the spectroscope it would be found to transmit nearly no other rays but the green. The Chairman then announced that the winter session of the club would begin on the 10th October, and that the nights of the meetings would be altered to Mondays at 8 o'clock, the chair being taken at 8.30 p.m. This change had been found necessary in order to secure the use of a larger room, the present one being inadequate, owing to the increased number of members.

**Rotherham.**—The monthly meeting was held on the 6th inst. Dr. F. B. J. Baldwin (President) in the chair. One new member was elected. The Bynoe printing-frame was introduced. The arrangement for holding the paper was much approved, but the question was asked as to the risk of the print moving in the larger

sizes. Information had been received relative to the Hill-Norris collodion plate, which had made its appearance during the month. Particulars of several photographic specialities were laid before the members. The fourth excursion of the season was arranged to take place on Friday, September 16th. The destination is Wingfield Manor, Derbyshire. The remainder of the evening was taken up in a profitable consideration of "questions," of which there were a considerable number. One member desired information as to the yellowing of one of the chloride of silver emulsion papers, and it was thought that in the process of toning the addition of fresh gold to an almost exhausted bath might have brought about the degradation.

**Sheffield.**—The monthly meeting was held on the 6th inst., Mr. E. J. Chesterman in the chair, when, after the routine business of the meeting and the election of Messrs. Toplis and Harrop as auditors, the new rules were brought forward and thoroughly discussed and satisfactorily arranged, when fifteen members gave in their names to join, which was considered very good for a commencement, after which the Secretary laid upon the table for inspection a new printing-frame by Beck and Co.; also Mr. Crowder showed a neat contrivance to act as printing-frame in case of emergency. Several members gave very good reports of the Paget Prize plates handed round at the last meeting, showing negatives and prints from same. The date for the receipt of pictures for the annual competitions was postponed until November 14th. Mr. E. Beck opened the discussion on "Instantaneous Photography," which induced a deal of valuable information.

**South London.**—Ordinary meeting on the 3rd inst., Mr. Maurice Howell, one of the Vice-Presidents, in the chair. At the conclusion of the usual formal business, the President, Mr. F. W. Edwards, read a paper on the life and works of George Tinworth, the famous terra-cotta sculptor, illustrated by a fine collection of forty lantern slides, which was much appreciated by the members and friends (150) present. Many requests for the repetition of the lecture have already been received by the President, who has consented to do so, and to increase the number of illustrations to sixty. It was announced that the judging of the prints from negatives on Paget plates was deferred until the next meeting. The winter session will open with a cinderella dance on the 3rd proximo.

**Wigan.**—Annual meeting on 7th inst. Annual report and balance-sheet presented. The latter showed a small balance on the right side after paying all expenses. In the report thanks were expressed to the Editors of the AMATEUR PHOTOGRAPHER and *Photography* for the loan of their 1891 prize lantern slides, and also to the Editors of the AMATEUR PHOTOGRAPHER, the *Practical Photographer*, and *Photographic Work* for gratis copies of these papers. The following officers were elected for the ensuing year:—President, Mr. J. A. E. Lowe; Vice-Presidents, Rev. J. S. Barnes, M.A., Mr. R. Wardman, and Mr. G. R. Newman; other members of Council, Messrs. J. H. Atherton, J. Smith, Wm. Heaton, B. B. Hartley, S. Richardson, H. Hill, and Percy Clark; Hon. Secretary and Treasurer, Mr. Fred Betley, 11, Swinley Road, Wigan. A small Sub-Committee was appointed to look out for a more suitable place of meeting.

**Woolwich Polytechnic.**—The usual fortnightly meeting was held on 7th inst. After several photographic questions had been discussed, a demonstration of the "Cold Bath Platinotype Process" was given by Rev. E. J. Doherty. A number of lantern-slides and prints by members were handed round and much admired. Next meeting Wednesday, the 21st inst., at 8 o'clock. Subject, "Lantern-Slide Making."

#### SOCIETIES' FIXTURES.

- Sept. 16.—LEWISHAM.—"A Trip to Norway with the Hand-Camera," Mr. W. C. Chaffey, sen.  
 " 16.—RICHMOND.—Informal meeting.  
 " 17.—PEOPLE'S PALACE.—Outing to Tower of London.  
 " 17.—LEYTONSTONE.—Informal meeting.  
 " 17.—EAST LONDON.—Excursion to Winchmore Hill.  
 " 17.—CROYDON.—Excursion to Limpsfield, Pain's Hill, and Hurst Green.  
 " 19.—LEEDS.—Review of the Summer's Work.  
 " 19.—S. LONDON.—"Photography in Natural Colours," Mr. W. Groves.  
 " 20.—N. LONDON.—"Practice Retouching," Redmond Barrett.  
 " 20.—HACKNEY.—Ordinary meeting.  
 " 23.—RICHMOND.—Informal meeting.  
 " 23.—OXFORD.—Outing.  
 " 24.—RICHMOND.—Excursion to Richmond and neighbourhood.  
 " 24.—BRIGHTON AND SUSSEX.—Excursion to Lewes.  
 " 24.—HACKNEY.—Members' lantern night.  
 " 24.—S. LONDON.—Excursion to Kew Gardens.  
 " 24.—HACKNEY.—Excursion to Hampstead.  
 " 24.—LEYTONSTONE.—Informal meeting.  
 " 24.—LIVERPOOL.—Excursion to Birkenhead Park.

**Charterhouse Science and Art Schools and Literary Institute.**—The winter session of this—one of the largest science and art schools in the United Kingdom—will commence on Saturday, September 24th, under the presidency of the Rev. Henry Swann, M.A. During the late session upwards of 1,000 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number nearly 700 presented themselves for examination, and were successful in obtaining a large number of class certificates, and also a fair number of honours certificates awarded by the Science and Art Department of South Kensington. Several students prepared for the Lond. B.Sc. (Int.) examination, and highly distinguished themselves. Instruction of a practical character is given in most of the sciences at a very nominal fee; whilst in art, at an equally low rate, students under the direction of five competent instructors can be advanced in their studies. Those who have leisure can at a very moderate charge attend the day classes in art. Day classes will also be held to prepare candidates for matriculation (Lond.), the clerical, medical (including dental), and other exams. Students who aim at becoming proficient in chemistry (organic and inorganic) have the opportunity of working in a well-fitted laboratory, capable of accommodating sixty students. Aspirants for university honours can at a very small expense be

assisted in their studies. Classes for matriculation, microscopy Latin, Greek, French, German, shorthand, and music are taught by well-qualified teachers. Opportunities for study of photography, etc., are to be continued this session. Full particulars of the classes may be obtained from C. Smith, organising Secretary.

**Chorley.**—In connection with the Polytechnic, Limited, recently established in this town, a camera club has been formed which will be known by the name of "The Chorley Polytechnic Photographic Society." The premises, which are at present undergoing extensive alterations, are conveniently situated in Fellery Street, almost in the centre of the town, and it is expected that the dark-room will be ready for use in the course of a few days. At the meeting held on Wednesday last, the 7th inst., the following gentlemen were appointed officers:—President, Mr. J. T. Brierley; Vice-President, Messrs H. R. Dorning, R. Berry, and William Dornan; Secretaries, Messrs. Jas. G. Welch and Wm. Waring; Treasurer, Mr. Richard Gill. Judging from the attendance and the number of members who have enrolled themselves at the preliminary meetings, we have little hesitation in saying there is every prospect of this becoming a most successful organisation. Anyone interested and desirous of becoming a member, is invited to send his name to either of the Secretaries, from whom all particulars may be obtained.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns **MUST** be received by **TUESDAY MORNING'S POST**.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

## QUERIES.

5812. **Lantern Screens.**—Will someone kindly say from experience what is the best material of a semi-transparent nature to use for the above, image showing through screen and for small sizes only, say 3ft. disc? Would tracing cloth do?—HENRY.

5813. **Mounting.**—Using mountant of gelatine as in Wall's "Dictionary," what is the best way to mount gelatino-chloride prints? My difficulty is that I get a narrow defect all along the edges of the print. How should prints be pressed down either to card or to album leaves?—HENRY.

5814. **Stirn's Camera.**—Will any reader kindly tell me of what the advertised enlarging apparatus for Stirn's detective camera consists? Also, if there is any similar camera on the market in which you have separate plates, as I usually fail in trying to intensify one or two of the negatives when they alone are under-developed?—MEDICUS, R.N.

5815. **Herzheim's Paper.**—Can anyone give the prescription for mixing the toning bath for Herzheim's gel.-chlor. of silver emulsion paper, and also the address of maker?—A. B. L.

5816. **Fungus.**—Can any reader of the AMATEUR PHOTOGRAPHER tell me the cause of fungus forming on the insides of my toning bottles, and taking all the strength out of the solution?—AMPHOT.

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## QUERIES UNANSWERED.

Sapt. 2nd.—No. 5801.

„ 9th.—Nos. 5807, 5808.

## ANSWERS.

5785. **Glaze on Prints.**—So far as we know, it would be impossible to obtain an enamel surface on emulsion prints without squeegeeing to a support, nor would it be an easy matter to make a varnish to apply with a brush—the best that could be done in this way would probably be to strain the print in a printing-frame, absolutely flat, and then coat with amyl acetate and pyroxilin varnish.—EDITOR.

5786. **Opera-Glass Lenses.**—The lenses could be

used for a fixed-focus hand-camera, but as they are not corrected for photography, allowance would have to be made for the difference of foci, and they would probably also require considerable stopping down. It would be far better to use a single achromatic lens.—EDITOR.

5790. **Instanto. Shutter.**—The speeds of this shutter are from about  $\frac{1}{4}$  to 1-15th of a sec., with less exposure for sky.—EDITOR.

5794. **Address Required.**—The Brixton and Clapham Camera Club meets at 376, Coldharbour Lane, Brixton. Mr. F. W. Levett, 74, Geneva Road, Brixton, Hon. Sec.—EDITOR.

5799. **Condenser.**—Clock-face condensers are a delusion and a snare, and are never satisfactory; far better to buy some ordinary ones. With a 10 in. condenser there would be considerable loss of light.—G. N.

5800. **Printing in Clouds.**—It is quite possible, by painting over the print, merely the outlines, with gamboge paint, and covering the rest of the print with opaque paper, to obtain very good results. The white line caused by black paper is merely want of experience.—EDITOR.

5802. **Gibraltar.**—Photography is prohibited at Gibraltar.—EDITOR.

5803. **Developing.**—While it is no easy matter to state definitely the cause of failure, without seeing a negative or two, it sounds rather as though under-exposure was the cause. If the querist will send up a negative we shall be glad to help him.—EDITOR.

5804. **Carbonate and Washing Soda.**—The difference between these two salts is that the former is the pure salt with a definite amount of water, whilst the latter is impure and contains a variable amount of water. It is said that the men who make it are paid by the amount of water they can get the salt to contain. If required for developing, however, the one acts almost as well as the other, only for careful work the pure salt should be used.—EDITOR.

5805. **Reducing Intensified Negative.**—Place the intensified negative in a freshly-made hypo bath for ten minutes; or else a still greater reduction may be obtained by using a 2 per cent. solution of cyanide of potash.—EDITOR.

5806. **Bleaching Prints.**—The slight bleaching with copper bromide means that some of the image is converted into bromide of silver, or a compound of bromide of silver and copper, which according to Liesegang, Stolze, and others is perfectly stable. It would be far safer to refix, and wash well after the bleaching, though.—EDITOR.

5796. **Chloride Printing.**—I hardly think that "Perplexed" will get a good finder under 3s., but Messrs. Sharp and Hitchmough, of Dale Street, Liverpool, have very good "Aptus" finder at 3s. 6d. It is a bi-concave lens, and shows objects at any distance always in focus, and wooden finders of the camera obscura pattern at 2s., but I recommend those at 3s. 6d.—THE GOWK.

5797. **Mottled Negatives.**—This probably arises from not rocking the dish during development.—THE GOWK.

5798. **Spotting.**—If the spots are transparent touch them out with Indian ink. Use a fine brush.—THE GOWK.

5800. **Positive Appearance.**—The appearance of positive seen on the glass side of your negatives is due partly to under-exposure and partly to under-development. All negatives show a certain amount of positive.—AMPHOT.

5810. **Copying.**—By photographing with a half-plate, if a wide-angle is at hand by all means use it, and give a short exposure.—AMPHOT.

5811. **Elizabeth's Oak.**—H. I. C. can have a photograph of Queen Elizabeth's Oak (half-plate) by writing to me, enclosing stamps for postage.—T. G. ALLEN, 6, Cranworth Road, Sheffield.

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE TUESDAY MORNING'S POST if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—ED. AM. PHOT.

F. COE.—We do not undertake to reply by post. Let us know where the portraits were taken, in the house, garden, or where, and send us up a negative, and let us know what developer you use, then we can help you.

W. E.—The price of the Desideratum quarter-plate lens is 24s. Hockins' address is New Inn Yard, Tottenham Court Road.

CATTON.—Bromide paper is, as a rule, coated in the roll of about three-quarters of a mile in length. Cadett, of Ashstead, Surrey, and Edwards and Co., The Grove, Hackney, sell coating machines which run into several hundred pounds. Let us know what you want to do, in confidence, and we may perhaps help you.

T. HEADMORE.—The simplest reducer is Belitzaki's. Dissolve 20 gr. of potassium ferri oxalate in 1 oz. of water, add 2 gr. of sodium sulphate, when dissolved add 7 gr. of oxalic acid and shake occasionally till the solution turns green, then pour off from the undissolved acid, then add 120 gr. of hypo and shake, lay the negative in water till soft, then in the reducer till reduced sufficiently, wash well and dry.

AMATEUR.—(1) At the price there is, we should say, nothing to beat it. (2) What price will you go to?

GEO. FELL, JUN.—So much depends upon the character of the picture that really nothing definite can be said. You may be surprised to hear that a yellow screen of particular shade will require at least three hours' exposure, and then if the plate was developed practically very little would be visible. To obtain the true rendering of some deep red and brown pigments, it is necessary to use a yellow screen of such a shade as to cut off all but yellow and red, and then allow these to act for a long time, and afterwards use a light screen with a short exposure to obtain the greens and blues. We should like to see a print, but we are afraid this would not be much assistance, unless we had the original to compare it with. Many thanks for the note, however.

LUX.—The most probable cause of your failure is that the tissue has been kept too long, and has become insoluble, though it may also happen that you have exposed so long that the whole film has become insoluble. Try a little slip of unexposed paper.

NOVICE.—We should say that the stains are due to the print coming in contact with hypo before toning.

H. H.—Medium isochromatic most decidedly.

D. J. G.—The prints should be washed before toning. Try Welford's bicarbonate bath, or else the one suggested in our correspondence columns this week.

G. E. T.—Good results can be obtained by using amidol with the films, but bromide must be used at least half grain to every ounce of developer. The results are fully equal to those from pyro and ammonia.

J. E. and W. W.—To obtain the best sunset effects you must use isochromatic plates, medium rapidity, and with these, under the other conditions named in your letter, we should say that 1-10th of a second would be sufficient. In developing keep down the pyro, and try for rather thin, soft negatives, or else you will get too harsh high lights. Be careful to remember that colour is useless to you; all you want is effective grouping of cloud masses.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence.

Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the *AMATEUR PHOTOGRAPHER*, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to Tuesday mid-day) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, *AMATEUR PHOTOGRAPHER*, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques of Postal Orders, made payable to *Hazell, Watson, and Viney, Ltd.*, 1, Creed Lane, London, E.C.

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 8d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**Background.**—Splendid new background, 8 by 7, flatted oils, garden grounds, value £2 2s.; what offers? photo sent.—Milburn, Photographer, Battle Hill, Hexham, Northumberland.

**Cameras, etc.**—Half-plate camera (Fallowfield), all movements, Eastman rollholder, and three slides, 5 guineas; approval; deposit.—Broomhall, St. Margaret's, Twickenham.

Who e-plate landscape camera, never used, cost £7 10s., will take £3 10s., or exchange for hand-camera.—Sewell Brady, Portsmouth Road, Long Ditton, Surrey.

**Exposure Meter, etc.**—Watkin's exposure meter, with book of instructions, 10s.; Kershaw shutter, half-plate, in perfect condition, 10s., 1892.—No. 353, office of this paper, 1, Creed Lane, E.C.

**Hand-Cameras, etc.**—5 by 4 Kodak, equal to new, 30 films, fitted to hold 100, a bargain, £8 5s.—264, Hainton Street.

Good hand-camera, and splendid lot of etoeters, also magic lantern and slides, the lot 40s., or offer.—H. Wright, 13, Russell Street, Rochdale.

Samuel's patent hand-camera, 3 1-8th by 2 3-8ths in thorough condition, 13s. 6d., bargain.—Howard, 13, Parkmore Terrace, Brighton.

Leather covered quarter-plate hand-camera, fitted with Ross' 4½ in. doublet, of finest definition, and shutter working between combinations, price 70s., lens alone listed 5½ guineas.—E. Smith, 28, Burford Road, Nottingham.

Optimus lantern-size hand-camera, leather covered, 3 double backs, Euryscope R.R. lens, f/6, 2 finders, good order.—Letters only to T., 379, Strand, W.C.

Hand-camera for sale, nearly new, Lancaster's omnigraph, 14s. 6d.—Colbourne, Lowburne, Melksham, Wilts.

**Lenses, etc.**—Dallmeyer's 6 by 5 rapid rectilinear lens, with iris diaphragm, cost £5 17s. 6d., cash price £4.—Parker, Chemist, Scarborough.

1892 Instantograph lens, good definition, bargain, 16s.—J. T. Titman, Alma Villas, Gosberton, Spalding.

Half-plate euryscope, 35s., half-plate R.R., 18s., quarter-plate portrait, 8s., as new, all really good lenses, and very cheap.—John Browning, 8, Longfield Avenue, Black Horse Road, Walthamstow.

Ross' portable symmetrical lens, 5 in. focus, cost 70s., sell 45s.—Main, 75, George Street, Aberdeen.

**Sets.**—Underwood's 1892 half-plate Instanto set, good as new, only 63s.—Ricketta, Cheltenham House, Stroud.

Underwood's Instanto half-plate camera, Ashford stand, five double slides, R.R. and W.A. lens, and complete apparatus for turning out photographs, £8; worth double.—Davies, 22, Market Square, Pontypridd.

10 by 8 camera, first-class maker, three double dark slides, folding stand, solid leather locked camera case, separate canvas case for slides, all in perfect condition, 10 guineas.—J. B. Adamson, Sunnyside, Prince's Park, Liverpool.

Half-plate set, complete, price £17 10s.; Euryscope wide-angle lenses, Optimus long-extension camera, four double slides, Newman shutter, tripod, and various sundries, good value.—Address, J. H. Twiddy, c/o Housekeeper, 68, Cheapside, E.C.

**Bargain!** International quarter camera, lens, tripod, one wood and two metal slides with adapter, in leather-bound case, makes magnificent lantern slides.—Write, Rev. Hedley, Borough Road, Middlebrough.

Complete half-plate outfit, comprising Scott's patent camera, one Darlot's rectilinear lens, one

Darlot's wide-angle lens, Eastman rollholder, three double backs, tripod, waterproof case with straps, Marion's lantern slide making camera, five enamelled dishes, spirit level, etc., all in first-class condition, cost originally about £23. Particulars on application to "Camera," Imperial Hotel, Darlington.

A bargain, Lancaster's half-plate instantograph, two dark slides, R.R. lens, by London Stereoscopic Co., and Thornton-Pickard time shutter working behind lens with speed indicator; approval, £4.—Mahoney, photographer, Cappoquin, Ireland.

Quarter-plate camera complete, consisting of tripod lens, shutter, and case, also three dished, two printing frames, and ruby lamp, cheap.—A. Partington, Molyneux Street, Longlight.

Quarter-plate mahogany camera, reversing back, two double dark slides, achromatic lens, and folding stand, first P.O. 12s. 6d., has the lot; whole-plate mahogany camera, reversing back, one double dark slide and whole-plate lens, 15s. the lot.—James, 9, Beesborough Road, Ilford, Essex.

S. Dalby Smith, St. Thomas Street, Weymouth, offers perfectly new whole-plate camera, every possible movement, one double dark slide, 55s.; rapid rectilinear for above, with shutter, 55s.; half-plate camera, every movement, good condition, 3 double dark slides, 50s.; approval with pleasure, for they are bargains, costing double.

Lancaster's half-plate International camera, Silver Ring R.R. lens, iris diaphragms, three Lancaster's double slides and three Tylar's metal, four-fold tripod, solid leather, baize-lined case, Optimus finder, focusing cloth, etc., in excellent condition, thoroughly sound, no approval, only wanting seeing, cost over 10 guineas, cash £7.—Thomas, "Lanteglos," Globe Avenue, Enfield.

**Sundries.**—Macintosh, misfit, gentleman's fashionable black Paramatta Inverness cloak, quite new, unsoiled, 28s., worth double; approval, with pleasure, state height.—P., 7, Dereham Road, Norwich.

Very handsome meerschaum and amber pipe in case, cost 22s. 6d., take 7s. 6d.; 6 white china silk hemstitched handkerchiefs (gentlemen's), from abroad, 10s., worth 25s., or exchange good quarter-plate camera.—Cam, 1, Vernmore Street, Liverpool.

Clearing-out ancient model gun, frigate, suit captain £10, lathe 2½ centres, bright head, 3 feet bed, 8 feet high, £2 10s.; also model marine copper tubular boiler, 16 tubes, pressure gauge, £6 10s.—Burt, 67, Forest Road, Dalston.

Vols. 1 to 9 *AMATEUR PHOTOGRAPHER*, handsomely bound, perfectly new, also several special numbers; what offers?—R. D., 30, Marefield Gardens, London, N.W.

## WANTED.

**Hand-Cameras, etc.**—Hand-camera wanted.

Lowest terms to Sewell Brady, Long Ditton, Surrey.

Wanted, a good hand-camera, also good enlarging lantern, address.—J. Twiddy, 68, Cheapside, E.C.

### Bargains in Hand Cameras.

—Kodak, No. 4, size 5 by 4, new spool of film, warranted finest condition, in leather case, take £7 17s. 6d., cost £11 7s. 6d.; Adams' Ideal hand-camera, twelve quarter-plates, finest rapid rectilinear lens, time and instantaneous shutter, as new, £5 15s.; Fallowfield's Facile, fitted rapid rectilinear lens, carries twelve quarter-plates, as new, £3 17s. 6d. Optimus magazine hand-camera, covered leather, carries 12 quarter-plates, finest Optimus rapid rectilinear lens, two finders, shutter, etc., as new, take £5 5s.; Talmer hand-camera, carries 12 plates, fine lens, two large finders, time and instantaneous shutters, as new, take 65s.; Steinheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, take 27s. 6d.; Griffiths' best quality hand-camera, carries six ½-plates, two sunk finders, good lens, pneumatic shutter, take 30s., cost 42s.; quite new, all above are warranted as described. On view, City Sale and Exchange Rooms, 54, Lime Street, corner of Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Cameras! Cameras! Cameras! Lenses!** Lenses! and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus of every description bought, sold, or taken in exchange. Inspection invited.

**Bargains in Lenses.**—15 by 12 rapid rectigraph lens, Silver Ring, iris stops, grand definition, take £5 17s. 6d., quite new; whole-plate

Voightlander's rapid rectilinear, fine definition, best order, 80s.; whole-plate Optimus rapid landscape lens, quite new, rotating stops, 35s.; whole-plate Lancaster wide-angle lens, rotating stops, 15s.; 8½ by 6½ Ross rapid symmetrical, Waterhouse stops, grand definition, as new, £4 10s.; Wray's 7½ by 5 wide-angle rectilinear, rotating stops, as new, 47s. 6d.; half-plate aluminium rapid rectilinear, by Parkes, Waterhouse stops, 30s.; half-plate Ross' portable symmetrical, rotating stops, 4 in. focus, finest order, 45s.; half-plate wide-angle, by Morley and Cooper, rotating stops, as new, 27s. 6d.; half-plate Ross' rapid symmetrical lens, as new, moveable hood, Waterhouse stops, take £3 17s. 6d.; Wray's landscape, Casket lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, take 70s.; Ross' c. d. v. portrait lens, rack and pinion, finest condition, 35s.; Shew's c. d. v. portrait lens, Waterhouse stops, rack and pinion, as new, take 21s.; Optimus 5 by 4 rapid Euryscope lens, by Perken, Son, and Rayment, Waterhouse stops, as new, 47s. 6d.; quarter-plate Optimus rapid rectilinear, by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

**Bargains in Cameras and Sets.**—12 by 10 camera, double extension leather bellows, wide-angle movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide changing box, for 24 plates, all changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; 7½ by 5 long-focus camera, by Gutz, wide-angle movement, leather bellows, reversing back, rapid rectilinear lens, and folding stand, set complete, £5 15s.; half-plate Underwood's Instanto, wide-angle movement, double extension, fitted rapid rectilinear lens, slide, and folding stand, £8 17s. 6d.; half-plate camera, by Houghton, all latest movements, grand article, fitted three double slides, rapid rectilinear lens, and double folding stand, £6 10s.; half-plate 1892 Instantograph camera, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, three-fold stand and case, take £8 10s.; quarter-plate Lancaster's Mervilleux set complete, 15s.; Lancaster's Convention set complete, camera, lens, shutter, slide, and stand, as new, 40s.; quarter-plate aluminium Instantograph set complete, quite new, camera, lens, slide, shutter, and stand, 50s.; quarter-plate Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order. On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

It is unnecessary to send an advertisement to the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.

**NEGATIVES** carefully retouched. Specimen negative retouched free. Terms on application.—Miss Agnes Miller, 20, Speedwell Street, Oxford.

**IMPORTANT TO AMATEURS.**—Negatives skillfully retouched. Printed in silver, gelatin-chloride, etc., and Enlarged. Also Developing, Copying, etc.—Terms strictly moderate.—Address, Wilfred Emery, 21, South Street, Baker Street, W.

**RICHARDS' Patent Corners**, for mounting photos, prints, scraps, etc., in albums, scrap books, and mounts; clean, convenient, ornamental, self-contained, and always handy. Ready gummed, price 1s. the box or by post 1s. 1½d.—F. Watson, 17, Dartmouth Street, Westminster, S.W.

It has long been one of the Utopian ideas to invent some instrument which shall enable images of objects to be telegraphed from a great distance. Last year an American, Amstutz, was reported to have accomplished this, but we have heard but little further of it. Edison, it is well known, has been busy on the same subject. But, according to *Figaro*, a young French chemist, M. H. Courtonne, deposited with the Académie des Sciences in 1889 a sealed report of his researches in this direction, and of which only from fear of being forestalled the main details are now made public.

M. COURTONNE, it is said, substitutes a dry plate for the diaphragm in an ordinary telephone receiver, and by some special apparatus has actually succeeded in transmitting the waves of light the same as sound waves are transmitted. R. E. Liesegang published last year a small brochure on the subject, which attracted a good deal of attention at the time.

PHOTOGRAPHY is rapidly replacing sketching in the hands of explorers. H. M. Stanley used photography on his last African expedition, and now Lieutenant Peary, who has just returned to America from wintering in the northern parts of Greenland, brings with him a number of photographs of arctic scenery, etc. The value of such photographs will be, of course, far greater from their greater truthfulness, as in sketching there is always the personal equation to discount, which is in some cases by no means inconsiderable.

THE personal equation, or the influence of the training and, in many cases, the wishes of the observer, is always an important consideration in observations of a scientific nature. In astronomy and microscopy this influence is always of great moment, and for this reason partly photographs are so much more to be relied upon than sketches.

WE have had a pathetic letter from the Secretary of a photographic society, who complains of the difficulty of providing sufficiently entertaining pabulum for the winter session. He says, "Some of our own members have responded well to my demands for papers, but what we want is a few experts who will stump the round of societies and give lectures." Our correspondent does not state whether he expects the experts to give their lectures free. This is an important point. We know two or three workers who are

**EDITORIAL DEPARTMENT.**—All Literary Contributions, Queries and Answers, Photographs for Competition or Criticism, Books or apparatus for Notice or Review are to be addressed to the EDITOR, AMATEUR PHOTOGRAPHER, 1, CREED LANE, LUDGATE HILL, LONDON, E.C. (All communications should reach the Editor on Tuesday.)

### TERMS OF SUBSCRIPTION.

UNITED KINGDOM.....	Six Months, 5s. 6d.....	Twelve Months, 10s. 10d.
POSTAL UNION .....	" " 6s. 6d.....	" " 12s. 6d.
OUT OF POSTAL UNION ..	" " 7s. 9d.....	" " 15s. 8d.

**TRADE ADVERTISEMENTS** are received up to Tuesday morning.

**PUBLISHING DEPARTMENT.**—All letters containing Subscriptions, Orders, Remittances, SALE AND EXCHANGE Advertisements, or other business matters for the AMATEUR PHOTOGRAPHER are to be addressed to the Publishers, HAZELL, WATSON, AND VINEY, LD., 1, CREED LANE, LUDGATE HILL, LONDON, E.C. SALE AND EXCHANGE Advertisements (at the charge of **Three Words for One Penny**) must be received by Tuesday evening's post to ensure insertion in the same week's issue.

**"Amateur Photographer" Monthly Competition, No. 41.**—**"INLAND SCENERY WITH AND WITHOUT FIGURES."** Latest day, Oct. 24th.—Prizes: Silver and Bronze Medal, with ribbon and clasp. One mounted print only to be sent in. Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, November 11th.)

being constantly pestered to give lectures or demonstrations; and, as one says, "What good does it do me?—I have to travel seven or eight miles, expend two or three shillings in fares, besides a lot of time, and then find that there are perhaps only twenty, or at the most thirty, amateurs to listen to me."

UNDOUBTEDLY there is a want in this respect, and we believe more advanced workers would willingly come forward with help if their expenses were guaranteed, and they were sure of getting a good audience. One of the inducements put forward by the P. S. G. B. in the affiliation scheme was, we believe, the circulation of papers to affiliated societies. Possibly if greater support were given to this scheme, and the expenses were guaranteed by the societies, more might be done in this way.

WE had ourselves an idea of formulating a series of lectures on elementary and practical subjects for the winter session, but want of time and the question of expenses has prevented us from doing so. If we did arrange such a scheme, would the societies respond? Now, please, honorary secretaries, don't all speak at once.

WE noted last week the issue of a new monthly by Elliott and Son. This week we have to record the issue of another monthly, called "Dry Plates," by Cadett and Neal, whose plates are reported on elsewhere in this issue. "Dry Plates" is an eight-page paper, which this month has some very useful notes on ammonia, and an article on Hurter and Driffield's Actinograph.

AT the present time there seems to be an increased energy in spiritualistic and kindred circles, and many proofs have been brought forward as to the existence of materialised spirits. Possibly some philistine may suggest that many of the effects are really due to the materialisation of spirits, and ardent ones too; but amongst the proofs have been shown prints and negatives in which the Mahatmas or materialised spirits are distinctly seen. Prof. Elliot Coues has collected about fifty of these spirit photographs, and has given a scathing exposition of the fraud, for fraud it is. No doubt many of our readers can show ghost-like negatives, which are due in part to over-exposure or under-development. But if they wish to amuse their friends it is no difficult matter to make these Mahatmas impress their image on the sensitive plate.

To produce a spirit on a plate, set up the camera and focus in the ordinary way on a person wrapped in a sheet or other article, such as these guardian angels usually attire themselves in, and placing the clothed spirit, slightly out of focus, against a dark background, give a short exposure, then cap the lens and allow the spirit to walk away. If one now places the real sitter in the centre of the focussing screen, and gives an ordinary exposure, one will find on development a materialised angel visible, and have one of these spiritualistic frauds. A well-known English clergyman has lately been quite conspicuous by his advocacy of these spirit photographs, and has actually had an exhibition of them in his vestry.

ON every hand we find evidences of the approach of winter, and this is particularly noticeable in societies, the Secretaries of which are now busy with their programmes. Evidence from other sides also is not wanting. The tech-

nical schools of the People's Palace will on the 26th inst. open their winter session, and of the subjects included in these classes is Photography, with Mr. Chas. W. Gamble as lecturer, Mr. Alfred J. Newton as assistant, and Mr. Wolfgang Arndt as instructor in retouching. From the syllabus we find that there are three courses: (1) elementary, technical, and practical photography, (2) an advanced course, and (3) a special afternoon practical instruction class.

BESIDES the above the City of London Y.M.C.A., of 186, Aldersgate Street E.C., will hold evening photographic classes on Fridays, under Mr. B. Foulkes-Winks, who will also give an introductory lecture on the 29th inst., for which any of our readers may obtain tickets on application to Mr. Foulkes-Winks at the above address. The fees for all the above classes are merely nominal.

WE have often been asked what is the use of these lectures, and we certainly can say that such lectures will form a sound basis for practical work. Though many men sneer at the scientific side of photography, there is not a doubt that a good, sound training in the science of chemistry and optics will do much to lighten the difficulties which are sure to be met with in practice, and no one with any artistic feeling will be the worse for such knowledge.

IN our correspondence columns appears a letter from Mr. Philip Thomas, the Hon. Secretary of the Cheltenham Amateur Photographic Society, suggesting a very good plan which we are sure will lead to better *camaraderie* amongst amateurs. We trust English societies will immediately respond, and we shall be glad to do all in our power to help the movement. Speaking on the authority of a *confrere* who has lately returned from the States, we are quite certain that not only the Chicago but also the other American societies will respond if applied to.

THE following are the dates we have fixed for our 1892 Lantern-Slides:—

1892.	1893.
Oct. 13.—Birkenhead	Jan. 2.—Richmond
" 18.—Birmingham	" 6.—Blackburn
" 21.—Burton-on-Trent	" 10.—Phot. Soc., Ireland
" 24.—Delph	" 13.—Munster
" 27.—Liverpool	" 17.—Cheltenham
" 29.—Tadmorden	" 23.—Devonport Cam. Club
Nov. 3.—Barrow	" 25.—" R. N. College
" 9.—Kendal	Feb. 3.—Stockton
" 14.—Ulster	" 7.—Newcastle
" 15.—Belfast	" 10.—Carlisle
" 18.—Preston	" 12.—Sunderland
" 22.—Rodley	" 17.—York
" 24.—Louth	" 18.—Bootham
" 28.—King's Lynn	" 22.—Stockport
" 30.—Yarmouth	" 23.—Oldham
Dec. 6.—Wolverhampton	" 27.—Sheffield Optical
" 9.—Warrington	March 1.—Crewe
" 13.—Manchester Am. Phot. Soc.	" 6.—Accrington
" 16.—Lewisham	" 14.—Hove
" 20.—Faversham	" 18.—Leytonstone
" 23.—Maidstone	" 21.—Sydenham
" 27.—Guildford	" 22.—Woolwich
" 29.—Sutton	" 28.—East London
	April 5.—Ramsgate

So far as possible, we have fixed the dates so that societies may be saved a heavy carriage. We trust that the Societies will endeavour to make these convenient, though if change of date is desired we will try to meet the same.

Those secretaries who have not sent booking fees are requested to do so at once.

EXHIBITIONS without number will be soon in full swing, and, as in past years, we have compiled a table giving the essential information about them.

WE have also received notice of the opening of the Todmorden Scientific Association's Photographic Exhibition on November 5th.

THE Exeter Amateur Photographic Society will hold an exhibition in the last week in November. Full details will appear later on. It will be open to all, amateurs and professionals, but the former only will be eligible for competition.

THERE is an old proverb which tells us we should look before we leap. Mr. Pickering, the Hon. Secretary of the Leicester Photographic Society, whose letter on toning gelatino-chloride papers we published last week, in which he offers to send a print toned by his method, did not look before he leapt into type, and the consequence is what he states in his letter of this week. Our readers will pity him and congratulate us.

### Chit-Chat.

IN these days of "scientific" exposure I am glad to note that a practical photographer like Mr. Bedding has the courage to advocate the study of the appearance of the image on the focussing screen, and the consequent cultivation of judgment in learning to correctly estimate exposure, rather than trust to the use of an exposure meter. He is quite capable of holding his own against the "disinterested" attack of the gentleman who seeks to question his method, without any championship of mine, but being a firm believer myself in the superiority of "judgment and brains" over any scientific jugglery yet invented for the purpose, I cannot let the opportunity pass of saying a word on the subject. One remarkable and to me significant circumstance is that the inventors of these ingenious instruments are rarely, if ever, *skilful practical photographers*; nor do we often find clever workers resorting to the use of such quasi-scientific accessories. Again, calculations arrived at by different instruments rarely agree. Only the other day I saw two amateurs calculating the exposure for a particular view, under precisely similar conditions, with exposure meters of different construction, and they respectively arrived at five and fifteen seconds as being the correct (?) exposure. *Verbum sap.*

I WONDER what our plate-makers think of the estimation of the relative speeds of plates given by a writer in the AMATEUR PHOTOGRAPHER recently. As one with a great capacity for "plate-spoiling," I should in several instances take great exception to the accuracy of the comparative speeds given. Seriously, such tables, to be of practical value, must be scientifically accurate, and, like Cæsar's wife, above suspicion, and the results obtained should be checked independently, *before publication*.

ANOTHER proposal for a new photographic society! When is the multiplication of societies to cease? They are already, in London, far too numerous, and in many suburban districts the amalgamation of neighbouring societies would be advantageous to all concerned. Let Mr. Wilton, who suggests a new society for Stratford, commu-

nicate with the Leytonstone Society. I had occasion, in an official capacity, to visit the exhibition of that young society last year, and I noticed that the work of some of the members showed great promise.

*Apropos* of photographic societies, the proceedings at technical meetings are frequently of such a character as to invite sarcastic comment. The "gift of the gab," if the Editor will pardon me the vulgarism, is unfortunately, the prerogative of but a few, and the natural result is that all the talking in not a few of the societies is done by one or two individuals with a degree of regularity which in most cases becomes almost monotonous. I would suggest to those gentlemen who know everything, or think they do, and are so eager to communicate the fact to their less fortunate fellows, that, in the interests of a society, much good might accrue by giving the younger and more diffident though possibly not less well-informed members, the opportunity of contributing to the common good, by answering queries and joining in discussions.

I HAVE read "Surgeon's" letter carefully, but I cannot see that he makes the case for hydroquinone any stronger than it was before. Your editorial comment, too, was rather unkind to a gentleman who tells you that Mr. W. K. Burton is "unscientific" and addicted to "rule of thumb" procedure!! Well, well, the poor professor is fortunately a long way off, so perhaps the force of the accusation will in some degree have spent itself by the time it reaches him. Seriously, I think all that you and the rest of the "presumed leaders" (!) in photography have done in regard to this developer is to recommend pyro to beginners in preference to hydroquinone, because of the greater tendency of the latter, in unpractised hands, to produce hardness and lack of gradation. To such advice no experienced photographer would take exception, though, of course, with care and skill, it is possible and easy to obtain both softness and gradation with hydroquinone.

NOTWITHSTANDING the mud throwing which has been indulged in from certain quarters, I understand that very little has stuck to the walls of the P. S. G. B., and that the success of the Exhibition will be equal to that of previous years. Lamentable though it be, the *fracas* of last year will doubtless be productive of good, for, undoubtedly, reform in the management and organisation of photographic exhibitions generally is greatly needed, and the suggestions upon this subject made by Mr. Horsley Hinton in the last issue of the AMATEUR PHOTOGRAPHER are deserving of the closest attention by all interested.

LAST week I wound up with a growl, this week I will conclude with a "purr," and it is a complimentary one too. It is the habit of some of your contemporaries to be continually lauding their own journalistic prowess; let me, "for this occasion only," call attention to the excellence of the last number of the AMATEUR PHOTOGRAPHER, both in literary matter and illustrations. Your readers, I am sure, do not overlook the fact that in photographic journalism, as in other things, quality is to be preferred to quantity.

CHATTERBOX.

Mr. A. E. Bailey, of Rose Bank, South West Road, Leytonstone, the Hon. Sec. of the Leytonstone Camera Club, will be glad to forward entry forms for the open classes of their exhibition, which commences on November 10th.

## NOTES ON COLOUR.

## III.—COLOUR CONSTANTS.

COLOURS as we know them, whether prismatic or pigmentary, have certain constants or properties, and these constants have considerable bearing upon our subject, therefore a brief consideration will not be out of place.

We have observed that certain wave lengths produce certain colours, and that these colours may be so accurately defined that when we speak of prismatic red of line A, we know exactly the tint in question. When all the waves of every length act upon the eye, we receive a sensation of white. Comparing any colour, whether pigmentary or natural, such as that reflected from a scarlet geranium, with the prismatic colours, it will be found that we never can find an exact match. The question is, why not? To match the tint of our geranium with the spectrum, it will be necessary to mix white light with the spectrum, because if we examine the light reflected from the scarlet geranium we find not a pure spectrum red, but a red mixed with a good deal of the other colours of the spectrum; or, in other words, all natural or pigmentary substances when illuminated by white light, reflect not only the particular colour of that substance or object, but also a good deal of white light. Taking an example to make the case plainer, we will suppose that we have an oil painting, or rather a broad band of oil colour, say green, a bright emerald green, we shall find that it is impossible to match this tint in the spectrum, but if we mix with the green of our spectrum a small proportion of white light by reflecting a beam of white light into it, we may match our pigmentary colour exactly. Approximately the result will be, assuming the amount of light reflected from the oil pigment as = 100, that 80 parts of spectrum green and 20 parts of white light will make our emerald green. Therefore, we may say, borrowing a term from the analytical chemist, that the light reflected from our pigment is adulterated with 20 per cent. of white light, and we thus obtain our first constant purity.

The next constant is not easy to determine. For this purpose we must have recourse to a difficult photometric calculation, by the aid of rotating discs. Thus we may have two colours which are equally pure; thus two emerald greens, both containing 80 per cent. of green light and 20 per cent. of white light, yet these two greens may not match, one being three times brighter than the other, and to equalise the two we must either illuminate the one with a feebler light, or the other by a more powerful light. Thus we find brightness, or luminosity, our second constant. Vierordt\* has made a series of experiments, the results of which are tabulated as follows:—

TABLE OF THE LUMINOSITY OF DIFFERENT REGIONS OF THE PRISMATIC SPECTRUM.

Colour.	Position.	Luminosity.
Orange ..	C line ..	12
Yellow ..	D „ ..	76
Yellow-green	D $\frac{1}{2}$ E „ ..	100
Green ..	E „ ..	37
Blue ..	F „ ..	12.8
Blue-violet	G „ ..	.8
Violet ..	H „ ..	.07

According to Eder† the relative brightness of the spectrum colours are given somewhat differently:—

Colour.	Position.	Luminosity.
Orange ..	C line ..	10
Yellow ..	near D „ ..	80
Yellowish-green	D „ ..	100

Colour.	Position.	Luminosity.
Green..	E line ..	30
Bright blue ..	F „ ..	10
Violet..	H „ ..	1

These tables will be referred to again, and special attention drawn to the same. The experiments necessary to determine the luminosity of colours by the aid of revolving discs are hardly within our province. For account of these see Maxwell's papers in "Philosophical Transactions," vol. cl., and Rood's "Modern Chromatics," pp. 35, 210, etc.

The third constant of colour is described by the word hue, that is to say the exact colour of the spectrum which is perceived by the eye. To accurately observe the third constant, a simple one prism or a direct vision spectroscopy may be employed, it only being necessary to use a special-eye-piece devised by Dalton, which is provided with an adjustable diaphragm which enables any set of wave lengths to be isolated at will and compared with a fixed scale.

Aubert, in his "Physiologie der Netzhaut," found that the eye was sensitive enough to detect an admixture of one part of white light in 360 parts of coloured light. He also determined that differences of  $\frac{1}{120}$  to  $\frac{1}{180}$  in luminosity could also be detected, and that an admixture of from  $\frac{1}{120}$  to  $\frac{1}{180}$  of a certain coloured light with another coloured light, gave rise to recognisable differences in hue or wave length. The estimation of the amount of coloured light in sunlight is not a difficult matter; it is only necessary to multiply the space occupied by the colour in the spectrum by its luminosity.

THE AMOUNT OF COLOURED LIGHT IN 1,000 PARTS OF WHITE SUNLIGHT.

Red ..	54
Orange red ..	140
Orange ..	80
Orange yellow ..	114
Yellow ..	54
Greenish yellow ..	206
Yellowish-green ..	121
Green and blue-green ..	134
Cyan blue ..	32
Blue ..	40
Blue-violet ..	20
Violet ..	5

1,000

From this table we note one curious fact, that the so-called non-actinic or visually active rays are in much greater proportion than the chemically active. Thus dividing the spectrum at yellowish-green, we find the total to be—visually active rays 769, chemically active 231. Attention to this particular point will be directed again later on.

## Letters to the Editor.

### STRIPPING GELATINO-CHLORIDE PRINTS.

SIR,—Mr. Craig assumes, somewhat cynically, that the average amateur has at least a few spoiled negatives which can be used for enamelling purposes, but if Mr. Craig's method be adopted throughout, I am afraid the operator will soon get through a pile of such negatives. The directions are: use a sharp-pointed knife and cut right through to the glass. Now, these cuts or knife thrusts leave their mark on the glass, and are faithfully reproduced on the enamelled surface. One or two fine hair lines are not of much account, but when they cross and re-cross each other, the plate bearing them, whether of glass, vulcanite, or iron, is certainly not suitable for enamelling prints.

If the glass plate be scrupulously clean, the dry print with its backing can generally be stripped by merely starting it with the point of a knife, while with the specially prepared iron plate I have

\* Poggendorff's "Annalen," vol. cxxvii., p. 200.

† "Ausführliches Handbuch der Photographie," Th. 3, p. 157-158.

had no difficulty in removing the print; in fact, they occasionally drop off if the plate be put in a warm place.—I am, yours, etc.,  
Edinburgh.  
J. A. FORRETT.

\* \* \* \*

## HYDROKINONE DEVELOPMENT.

SIR,—Replying to your correspondent, "Surgeon," my objection to hydrokinone is exactly that of yours, viz., it makes the high lights too hard.

My strong conviction, based upon a considerable amount of experience and study of the question, is that out of ten exposures made nine are over-exposures. I, of course, exclude hand camera work.

I quite agree with "Surgeon" that bromide is not needed to anything like the extent to which it is used; indeed, scores of plates are made to appear under-exposed and hard by its misuse.

Years ago I was much struck by Mr. B. J. Edwards's suggestion to develop plates with a solution weak in pyro and bromide but normally strong in alkali. This rushes up a thin flat image, when the solution is poured off and another applied, strong in pyro and bromide but weak in alkali, which soon intensifies the image to the required density. That this is the best method known to get a properly graduated negative there is little doubt, but then Mr. Edwards, Captain Abney, and others, who have on various occasions enliterated the method, forgot to tell us that such a mode of development was only possible with plates rich in quality and quantity of emulsion. Hence, no doubt, the reason why this system is not better known. My test of a good plate is that after prolonged development, keeping the image very weak in contrast, density may be got readily when required. Few of the cheap plates will do this.

The advantage of such a style of development is that the negative is even and soft, from the highest lights to the deepest shadow, whereas by the usual method of using a normal developer there is a considerable leap from the highest lights to the next series. To make my meaning clear, let us suppose the gradation to be represented by a flight of steps twenty in number, the topmost step representing the highest light and the bottom one the deepest shadow. Then, whilst Edwards's method would give us an almost perfect gradation throughout, we, with a normal developer, would get scarcely anything between the highest lights and half-tones, i.e., tones represented by steps No. 3, 4, and so on to say 10 would be missing. Now kinone makes matters still worse, for steps between say 2 and 15 would probably be missing. If the plate is poor in silver, then by all means use it; but the better a plate is, the worse does kinone suit it.

For some months past I have been using Rodinal, and as my work includes interiors, exteriors (often 15 by 12 size plates), instantaneous, and studio work, I think I may claim to know something of it; and all I can say is that for all camera work it is simply perfect.

I am aware Mr. Welford and others say that density cannot be had with it, but that is certainly not the case with me. I use the hand-camera sometimes, mostly working at highest speed of Kershaw shutter, stop  $f/11$ , and can get full density in three minutes if necessary, but I prefer to develop about that time with a normal strength (one in forty-five) for that time, pour off and apply a fresh solution of one in eight or ten. This soon brings density. I have also tried Amidol, and after repeated trials can see no advantage whatever over Rodinal, the latter being rather quicker of the two and quite as powerful.

With Rodinal I only use bromide for interior work, over-developing a little, and then slightly reducing so as to get a good clear negative.—Yours truly,  
H. WILKINSON.

\* \* \* \*

## CAMERA FITTINGS.

SIR,—I trust the suggestions contained in this letter will not put "H. J." to too much trouble, but I think the information desired would materially assist many of your readers besides myself, in trying their hand at camera-making.

Would "H. J." kindly tell us from what firm or firms the metal fittings for the items treated upon can be obtained, and if in aluminium as well as brass?

Also what tools are necessary for the satisfactory production of the cameras, etc.? I have a few rough joiners' tools, with which I am in some degree proficient, but very few of them, I fear, are at all applicable for camera work, not being sufficiently delicate.

If "H. J." will go so far as to enlighten us on these points,

I have no doubt he will confer a favour on many of your readers, besides—Yours, etc.,  
G. T. W.

[The above letter was unfortunately received too late for us to obtain an answer for this week's issue. Messrs. Lancaster, Fallowfield, Adams, Platt and Witte, Park and Lonsdale Bros., besides numerous other dealers, offer brass fittings for cameras. We are not aware that any firm have placed aluminium fittings on the market, though they could doubtless be obtained from Messrs. Beck or Watson.—EDITOR.]

\* \* \* \*

## EASTMAN AND ILFORD PRINTING-OUT PAPER.

SIR,—I was not aware what a storm I was invoking on my head when I offered to send a specimen print to any of your subscribers who might wish for sample of toning of gelatino-chloride paper by my process. The result so far (Monday) is that I have received 187 letters from all parts of the country, and some from Germany and the Continent as far as Frankfort. I am endeavouring to supply them, but I am afraid the great number to be toned will almost preclude that attention I should like to give them personally, as business claims compel me to depute the various processes to others. If, therefore, any of my correspondents receive prints which are not as satisfactory as they were led to expect, they must kindly excuse me, and to such I would say, try the process for yourself and be convinced.

It must be gratifying to you, and satisfactory to your advertisers, to know that your useful weekly has such an international circulation.—I am, yours, etc.,  
H. PICKERING

(Hon. Sec., Leicester Phot. Soc.)

\* \* \* \*

## AFFILIATION OF SOCIETIES SCHEME.

SIR,—It has appeared to me for some time past that, with the powerful assistance of the photographic press (which seems to be seldom invoked in vain), the practical usefulness of the host of societies throughout the United Kingdom might be greatly extended if some system of reciprocity could be introduced with regard to the use of dark-rooms by visitors, and their admittance to meetings, excursions, etc. To put the scheme into practice, I propose that the secretaries of such societies as are willing to throw their premises open to all other societies who reciprocate should write to me giving particulars of the conveniences which visitors may expect to find there. These societies would then be classified, and I would send a full list to the photographic journals. All the secretaries interested would thus be put in possession of the fullest particulars of the resources of each society affiliated. A system of freemasonry would thus be initiated which could not fail to make the practice of amateur photography still more pleasant and fascinating. Most of us when visiting a strange town will appreciate the advantage of being able to change plates, and possibly develop without fuss or favour, to say nothing of the introductions to local amateurs in a position to give much useful local information and assistance. I cannot but think that if this idea be carried out, and perhaps enlarged upon later, it must prove of general benefit, and perhaps do something towards preventing the disappearance of some of those societies which are missed from our midst from time to time.

I see no reason why such affiliation should be restricted to British societies only; for instance, will Chicago societies reciprocate?

Perhaps members of societies will draw the attention of their secretaries to this letter and urge action?—Yours truly,

PHILIP THOMAS.

Secretary, Cheltenham Amateur Photographic Society.

## General and Photographic Chemistry. — VIII.

By E. C. CONRAD, F.C.S.

—

### THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.—(Continued).

#### THE HALOGENS.

THIS term, derived from the Greek, signifies producers of sea salt; it is applied to a group or family of four elements named chlorine, bromine, iodine, and fluorine. They all unite with one equivalent of hydrogen, producing important acids, and their potassium and sodium salts are analogous

in physical properties to sodium chloride or common salt. The first three elements more especially show a very close relationship in chemical action, while their physical characteristics exhibit a gradational difference; thus at ordinary temperatures chlorine is a gas, bromine a liquid, iodine a solid. In chemical activity and atomic weight they come in the same order, chlorine being most active, with a weight of 35.5, and iodine the least active, with a weight of 126.9, bromine occupying a central position in activity, with a weight of 80.

#### CHLORINE (Cl=35.5).

**Oc.:** Chlorine is never found free in nature, but always combined with metals, forming chlorides of which the most important is sodium chloride or common salt, which forms the principal part of the soluble matter contained in sea-water, and also exists in many springs and in large beds as rocksalt in many parts of the world, especially Cheshire, Austria, Russia, and America. **M.:** Chlorine can easily be obtained—(1) By gently heating a mixture of sodium chloride, manganese dioxide, and dilute sulphuric acid; Eq.:  $2\text{NaCl} + \text{MnO}_2 + 2\text{H}_2\text{SO}_4 = \text{Na}_2\text{SO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O} + \text{Cl}_2$ . (2) By heating a mixture of manganese dioxide with hydrochloric acid; Eq.:  $\text{MnO}_2 + 4\text{HCl} = \text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2$ . **P.:** Chlorine is 2.4 times heavier than the air, and water dissolves about twice its volume of the gas. It must therefore be collected by downward displacement. Chlorine is a yellowish-green gas of a pungent odour; it attacks the membrane of the throat, producing sickness, and even death if inhaled in large quantities. Under a pressure of six atmospheres at  $0^\circ\text{C}$ . the gas is condensed to a yellow mobile liquid of S.G. 1.33. A saturated solution of the gas on cooling deposits a crystalline compound, having the composition  $\text{Cl}_2 \cdot 10\text{H}_2\text{O}$ ; and if this is gently heated in a tube closed at both ends the gas can be liquefied by its own pressure. Chlorine is a very active chemical agent; thus phosphorus bursts into flame in the gas, and arsenic, antimony, copper, iron, etc., will when finely divided burn in it, forming chlorides. Chlorine also combines directly, at the ordinary temperatures, with many compounds, such as sulphur dioxide; but its most remarkable property is its intense affinity for hydrogen. A mixture of the two gases combine with explosion on exposure to sunlight, forming hydrochloric acid,  $\text{HCl}$ . A lighted candle placed in an atmosphere of chlorine will continue to burn with a dull, very smoky flame, the chlorine combining with the hydrogen of the wax to the exclusion of the carbon. A paper moistened with turpentine  $\text{C}_{10}\text{H}_{16}$ , and introduced into the gas, will often burst into flame from the energy of the combination of the hydrogen and chlorine, while the carbon is given off as a dense black cloud. Chlorine gradually decomposes water in sunlight, forming hydrochloric acid and liberating the oxygen. If there is any substance present that can combine with the liberated oxygen, which being in the nascent state is very active, the action goes on rapidly even in the dark. Thus chlorine acts as a bleaching agent, a disinfectant, and an oxidising agent in the presence of water, by setting free the oxygen which oxidises the colouring matter or other substances present.

**Test.**—(1) All chlorides heated with manganese dioxide and sulphuric acid give chlorine gas. (2) Any soluble chloride gives with free nitric acid and silver nitrate a white precipitate of silver chloride ( $\text{AgCl}$ ), which is easily soluble in ammonia.

**HYDROCHLORIC ACID,  $\text{HCl}$ =36.5.**—**Syn.:** Muriatic acid, spirit of salt. **Oc.:** In small quantities in the exhalations from active volcanoes. **M.:** It has been already noticed the chlorine and hydrogen gases combine with explosion in sunlight to form this acid, but if the mixed gases be exposed

to diffused light this combination takes place gradually. It is usually prepared by heating a mixture of sodium chloride with sulphuric acid, Eq.:  $2\text{NaCl} + \text{H}_2\text{S} = \text{O}_2\text{Na}_2\text{SO}_4 + 2\text{HCl}$ . Any chloride heated with sulphuric acid will give a similar reaction. **P.:** Hydrochloric acid is a colourless, irrespirable, incombustible gas, of a penetrating odour. Under great pressure the gas is condensed to a colourless liquid of S.G. 1.27. If the gas is passed over heated manganese dioxide, both are decomposed into chlorine, water, and manganese chloride, Eq.:  $4\text{HCl}_2 + \text{MnO}_2 = \text{Cl}_2 + 2\text{H}_2\text{O} + \text{MnCl}_2$ . Water at the ordinary temperature dissolves about 450 times its volume of hydrochloric acid gas, forming a strong acid solution of S.G. 1.21, which fumes strongly in the air, and gives off large quantities of the gas on gently heating. After the excess of gas has been expelled, a point (varying with the pressure) is reached at which the composition of the solution is unchanged. At ordinary pressures a constant proportion of acid and water distil over together at  $180^\circ\text{C}$ ., the distillate having a S.G. of 1.1, and containing 20 per cent. of the gas. Unless otherwise mentioned, hydrochloric acid always means a solution of the gas. Thousands of tons of this acid are produced every week as by-products in the manufacture of sodium compounds, but this crude acid is very impure, being of a yellow colour, and generally containing iron, arsenic, sulphuric acid, and some chlorine gas. This impure acid can be used for preparing chlorine, but for other purposes a pure, colourless solution should be used. As a reagent, an acid of S.G. 1.16 diluted with three times its bulk of distilled water makes a convenient strength.

**Action of Hydrochloric Acid on the Metals.**—Metals not acted on:—Silver, mercury, arsenic, gold, platinum. Metals slightly dissolved: Lead, antimony, copper, bismuth, tin. Metals quickly dissolved: Iron, aluminium, chromium, manganese, zinc, nickel, barium, calcium, etc. All metals on dissolving form a chloride, and hydrogen is always set free.

**Solubility of Chlorides.**—All the chlorides, with the following exceptions, are soluble in water. Lead chloride,  $\text{PbCl}_2$ , soluble in 140 parts of cold water, and readily in boiling water. Copper chloride,  $\text{Cu}_2\text{Cl}_2$ , almost insoluble in water, soluble in ammonia, hydrochloric acid, and in a solution of sodium chloride, silver chloride,  $\text{AgCl}$ , insoluble in water, soluble in ammonia. Mercury chloride,  $\text{Hg}_2\text{Cl}_2$ , insoluble in water, decomposed by ammonia. Gold and platinum chlorides,  $\text{AuCl}$ ,  $\text{PtCl}_2$ , are almost insoluble in water;  $\text{AuCl}_3$  and  $\text{PtCl}_4$  are soluble in water. It will be noticed that most of the insoluble chlorides are those of metals not acted on directly by hydrochloric acid; many of these are formed by the action of the acid on a salt of the metal. Ex.: silver chloride from silver nitrate. Eq.:  $\text{AgNO}_3 + \text{HCl} = \text{AgCl} + \text{HNO}_3$ .

**U.:** Hydrochloric acid is used as a solvent, and for the preparation of chlorides and chlorine gas. **U.P.:** A dilute solution is used for clearing platinum prints by dissolving out the ferric oxalate, and for a variety of minor uses.

**Tests.**—The same as those given under Chlorine.

**AQUA-REGIA OR NITRO-HYDROCHLORIC ACID.**—**M.:** By mixing one part of strong nitric acid with three parts of hydrochloric acid (it should be prepared as required). The nitric acid acts on the hydrochloric acid to form free chlorine, which dissolves in the acid liquid, which quickly becomes yellow, and after a time orange-red. **U.:** To dissolve gold, platinum, and some of the rare metals which are not dissolved in either of the acids separately, and also as a powerful oxidising agent in analytical chemistry. All the metals and most compounds are soluble in aqua-regia, with the following exceptions: the sulphates of barium, strontium, calcium, and lead, the chlorides of lead and silver, silica and

most silicates, stannic oxide, calcium fluoride, sulphur and carbon, and a few ignited or native oxides.

**OXIDES AND OXYACIDS OF CHLORINE.**—A list of these acids has already been given in the introduction. The following are their most important properties and compounds.

**CHLORINE MONOXIDE OR HYPOCHLOROUS OXIDE,**  $\text{Cl}_2\text{O}=87$ .—M.: By passing a slow current of chlorine over well-cooled mercuric oxide. Eq.:  $\text{HgO} + \text{Cl}_2 = \text{HgCl}_2 + \text{Cl}_2\text{O}$ . P.: A yellowish-green gas, easily decomposed. By the application of cold it can be condensed to an orange liquid which explodes on the slightest increase of temperature. Soluble in water, forming.

*Hypochlorous Acid*,  $\text{HClO}=52.5$ .—M.: (1) By dissolving the previous oxide in water. Eq.:  $\text{Cl}_2\text{O} + \text{H}_2\text{O} = 2\text{HClO}$ . (2) By passing chlorine into water containing calcium carbonate in suspension. Eq.:  $\text{CaCO}_3 + \text{H}_2\text{O} + \text{Cl}_2 = \text{CO}_2 + \text{CaCl}_2 + 2\text{HClO}$ . P.: A yellow coloured liquid, smelling of chlorine. This acid has a very powerful bleaching and oxidising effect, being twice as powerful as chlorine. It acts on the metals, converting some into oxy-chlorides, others into oxides, and a few into chlorides. Its salts are termed hypochlorites, and the most important is calcium hypochlorite,  $\text{Ca}(\text{ClO})_2$ , the active principle of bleaching powder.

*Chloride of Lime, or Bleaching Powder.*—This important compound, for which the empirical formula  $\text{Ca}_3\text{H}_6\text{O}_6\text{Cl}_4$  can be given, appears to be a definite chemical compound, the exact formation of which is not understood. Water decomposes it into calcium hypochlorite, calcium chloride, and hydrate and water. Eq.:  $\text{Ca}_3\text{H}_6\text{O}_6\text{Cl}_4 = \text{CaH}_2\text{O}_2 + \text{CaCl}_2 + 2\text{H}_2\text{O} + \text{Ca}(\text{ClO})_2$ . Carbonic acid also acts in somewhat the same way, therefore bleaching powder decomposes if exposed to the air after some time. M.: Lime free from iron and oxides of manganese is burnt and spread out to a depth of about eight inches and carefully slaked with water, about five gallons to each hundredweight. Too little water causes chlorides and chlorates, instead of the bleaching compound, to be formed, and too much water reduces the strength of the product. After being properly slaked, the lime is sifted and spread on shelves in a series of chambers composed of slabs of stone cemented together, and dry chlorine gas is passed over the prepared lime. The chlorine must not be absorbed too fast or heat is developed and chlorate formed. The time occupied varies, for a ton of lime to be saturated with chlorine would take on an average from 36 to 48 hours.

The amount of available chlorine in good bleaching power varies from 35 to 40 per cent.; this is not more than half the chlorine present, as that combined as calcium chloride is quite useless. U.: Largely used as a bleaching agent and also as a disinfectant. U.P.: With gold chloride in toning prints, the hypochlorite being converted into calcium chlorate and metallic gold set free.

*Tests for Hypochlorites.*—Their solutions bleach litmus or indigo. Dilute hydrochloric acid decomposes them with evolution of chlorine.

**CHLORINE TRIOXIDE,**  $\text{Cl}_2\text{O}_3=119$ . M.: By heating arsenious and nitric acids with potassium chlorate, the reaction takes place in two stages, nitrous acid being first formed. Eq.: (1)  $\text{H}_3\text{AsO}_3 + \text{HNO}_3 = \text{H}_3\text{AsO}_4 + \text{HNO}_2$ . (2)  $2\text{HNO}_2 + 2\text{KClO}_3 = \text{H}_2\text{O} + 2\text{KNO}_3 + \text{Cl}_2\text{O}_3$ . P.: A heavy yellowish green gas, decomposed by sunlight or if heated to  $50^\circ$ . Can be condensed in a freezing mixture to a reddish mobile liquid of S.G. 1.38, which explodes on warming above  $0^\circ$  C. Five parts of the oxide dissolve in 100 parts of water, forming a yellow crystalline hydrate, which is gradually converted into *Chlorous Acid*,  $\text{HClO}_2$ . This acid forms salts called chlorites, which are crystalline compounds, soluble in water. They are all easily decomposed and have the property of bleaching.

**CHLORINE TETROXIDE**  $\text{Cl}_2\text{O}_4=135$ . M.: By gently adding strong sulphuric acid to potassium chlorate. Eq.:  $3\text{KClO}_3 + 2\text{H}_2\text{SO}_4 = \text{KClO}_4 + 2\text{KHSO}_4 + \text{H}_2\text{O} + \text{Cl}_2\text{O}_4$ . P.: A yellow-coloured gas of an aromatic odour. It can be condensed to a liquid and at a very low temperature to a solid. It is slightly soluble in water, and bleaches powerfully; its solution does not form a corresponding acid, but is decomposed by the alkalis, forming a mixture of chlorite and chlorate. It is a very dangerous substance, being liable to sudden decomposition, producing most violent explosions.

**CHLORINE PENTOXIDE,**  $\text{Cl}_2\text{O}_5$ , and **CHLORINE HEPTOXIDE,**  $\text{Cl}_2\text{O}_7$ , corresponding to the following acids are at present unknown.

**CHLORIC ACID,**  $\text{HClO}_3=84.5$ . M.: (1) By adding dilute sulphuric acid to baric chlorate. Eq.:  $\text{Ba}(\text{ClO}_3)_2 + \text{H}_2\text{SO}_4 = \text{BaSO}_4 + 2\text{HClO}_3$ . (2) By adding hydrofluosilicic acid to potassium chlorate. Eq.:  $2\text{KClO}_3 + \text{H}_2\text{SiF}_6 = \text{K}_2\text{SiF}_6 + 2\text{HClO}_3$ . P.: Colourless, syrupy liquid, with a chloroid smell. It has a strong acid reaction, and exerts a powerful bleaching action. The concentrated acid easily decomposes on boiling, and gives a solution of perchloric acid and evolves chlorine and oxygen. It forms a series of salts called *chlorates*, the most important of which is

**POTASSIUM CHLORATE,**  $\text{KClO}_3$ .—M.: By passing chlorine into a warm, concentrated solution of caustic potash. Eq.:  $6\text{KHO} + \text{Cl}_2 = 5\text{KCl} + 3\text{H}_2\text{O} + \text{KClO}_3$ . On a large scale it is prepared by passing chlorine through milk of lime (slake lime suspended in water) contained in earthenware vessels fitted with sloping shelves. The chlorine enters at the bottom, and is slowly passed through the liquid, forming calcium chlorate, which is decomposed by potassium sulphate. The potassium chlorate is separated from the potassium chloride by successive recrystallisations. P.: Crystallises in anhydrous six-sided plates; soluble in sixteen parts of cold or two parts of hot water, insoluble in alcohol. On heating, parts with all its oxygen. U.: As a source of oxygen. Largely used in the manufacture of fireworks and lucifer matches, also in percussion caps with fulminate of mercury and other substances. U.P.: In the platinotype process, to increase contrast. *Tests for Chlorates.*—Solid chlorates are decomposed by heat, giving off oxygen or oxygen and chlorine. Warmed with strong sulphuric acid they decompose with a series of explosions (use only a small portion of the salt, and turn the mouth of the tube away from the person). The adulteration of potassium chlorate with potassium chloride can be detected by dissolving in water and adding silver nitrate solution; a white precipitate shows the presence of the chloride.

**PERCHLORIC ACID,**  $\text{HClO}_4=100.5$ .—M.: By the action of strong sulphuric acid on potassium perchlorate. Eq.:  $2\text{KClO}_4 + \text{H}_2\text{SO}_4 = \text{K}_2\text{SO}_4 + 2\text{HClO}_4$ . It can also be manufactured by boiling chloric acid, or by the action of sulphuric acid on the chlorates. P.: It is a colourless, fuming liquid of S.G. 1.78. It is an exceedingly powerful oxidising agent; placed on wood, paper, or charcoal, it at once sets them on fire. It attacks the skin, producing very painful wounds. It combines with water with a hissing sound, producing a crystalline hydrate which is soluble in excess of water, forming a thick oily liquid, boiling at  $203^\circ$  C., and containing 72 per cent. of the acid. Its salts are called perchlorates, and are all, with the exception of the potassium salt, easily soluble in water. This salt is only soluble with difficulty, being one of the most insoluble of the potassium compounds.

**CHLORINE AND NITROGEN.**—By the action of chlorine or hypochlorous acid on sal-ammoniac, an oily liquid is formed which explodes with great violence.

(To be continued.)

# How to Make a Set of Photographic Apparatus.

By H. J.

## CHAPTER VII.

### THE HAND-CAMERA—(Continued.)

In the last chapter we got as far as fixing the plate box on the tapes, and making it work properly; supposing that this is now finished, we will proceed with the next part, the swinging frame L, in which the plates are exposed. This is made up of three pieces as shown in fig. 56, A being the

FIG. 53.

front, through which the plate is exposed, B the middle part open at the top for admission of plate, and C the back, simply a solid piece. We will make A first; it can be made of either wood or ebonite, the latter of course being the lightest, and must be  $4\frac{3}{4}$  in. by 4 in. when finished, the opening being  $4\frac{1}{16}$  in. by  $3\frac{1}{16}$  in., and in the centre both ways. B, which must now be made, is the same size outside, but the opening must be marked out  $4\frac{1}{4}$  in. by  $3\frac{1}{4}$  in. full, also centrally both ways, and when cutting it out, the marks must be cut through, thus cutting out one side as shown. The thickness of this piece (B) must be a trifle under an eighth of an inch; any thickness of plate will then enter without trouble. The back C will be understood without any explanation. The three pieces can now be glued together and left under pressure until the glue is dry, when a few fine screws can be inserted from each side. The stop P can now be screwed on to division K, just below the slot; the correct place for it is found by measuring the back of the frame just made, and fixing P the same distance below the slot, so that when the frame is resting on it, the two apertures coincide.

FIG. 54.

Now take the two brass bearings (R), and screw them on back of frame, one at each side, or more correctly speaking one at each end close to the outside edge. The camera must now be marked on the outside, at the exact position of slot in K, and also of stop P, then by standing the swinging frame on end on outside of camera, in the same position it will be in on the inside, when resting on the stop with the open side close to K, and the aperture opposite the slot, the proper place can be found and marked for the spindle which runs through camera and on which the frame swings. This must be marked on each side, and the holes bored through, and a small brass plate let in flush with sides, with corresponding holes for bearings. The spindle itself is formed of a square piece of steel filed round at the ends, and must be long enough to project about a quarter of an inch on one side for the handle to swing frame by, S, fig. 49. This,

FIG. 55.

which can now be riveted on, I make of a small hinge clip, the same as are used for dark slides; the hinge part folding down into a slot made for it, thus holding the inside frame either vertical or horizontal. Before riveting this hinge on spindle, the brass plate for bearing must be taken out of camera and placed on spindle; then the hinge riveted on; the swinging frame can then be placed in camera, and the spindle passed through and the plate screwed to side again, when it will fix spindle in its place. A negative or a plate or two of some kind (quarter-plate size, of course) had better be placed in plate box, and transferred to the exposing frame and back again a time or two, to see

FIG. 56.

if it goes smoothly, which it will do if my instructions have been understood, and followed so far. If it does not, it must be made to do so before going any further, and then, with the frame in a horizontal position resting on stop P, mark where the clip of hinge S comes, and cut a small slot, so that it can be pressed in and so fix it; then turn it up, and cut a similar slot at right angles to the other to hold the plate in position for exposing. These slots must not be cut through the side of camera, but only in just far enough for the clip to enter.

FIG. 57.

The stop M must now be made. It consists of a piece fitted closely between sides of camera, about 2 in. wide and  $\frac{1}{4}$  in. thick; and another piece fixed along the middle of it, deep enough to stop the swinging frame; this size can be obtained by measuring the distance that bottom of frame is from bottom of camera, when the former is in a vertical position, and making M about a quarter of an inch higher. If this was only required to stop the plates in one place, it would simply be screwed to the bottom of camera; but as we

FIG. 58.

want it to form a swing-back as well, some other arrangement is necessary. The very simple method which I use is shown in fig. 58, which shows the bottom side of the thin piece mentioned above. As will be seen, a trench is cut out about an inch wide and one-sixteenth of an inch deep. A small hole is made with a bradawl inside of camera close to the bottom to take the end of lever T, and in the other side of camera a slot is cut (also close to the bottom), just large enough for lever to go through, and about  $1\frac{1}{2}$  in. long. The middle of this slot and the small hole opposite must be in the centre of M when the plate-holder is vertical, and in a line with these, across bottom of camera, a small centre-bit hole must be bored in the middle, or, perhaps, you will understand better if I say, at an equal distance for each side. Now screw the lever to the wood in the same place as shown in fig. 58, that is just in the middle of trench, and the small end projecting about one-eighth of an inch; then take screw out again, and run lever through the slot inside of camera, place the

FIG. 59.

piece of wood inside in its proper position, and insert the screw in the same hole as before. It will now be seen that when the end of lever is in the middle of slot inside of camera the plate will be vertical, but by pushing the lever either way, and swinging exposing frame close up to M, a swing-back is formed, so that the camera may be directed either up or down and the plate still be vertical. When using the swing-back the clip outside will not fit into its slot, but must be held firmly while the exposure is made.

FIG. 60.

We now come to the focussing and rising front arrangement, as it is both together. The focussing is managed in the same way as the swing-back, therefore fig. 58 will serve to illustrate them both, only as the range of focus will be much longer than the other, the bottom piece will have to be 4 in. wide, and the slot in camera side through which lever projects will be 3 in. long; this will give a range of focus from  $3\frac{1}{2}$  to 5 in. This part then is understood to be finished, and we will get on with mounting the lens. For this make two pieces as U U, fig. 59, with grooves on the inner edges as shown; screw these on to the bottom piece, already fitted as shown in fig. 47, leaving about 2 in. between them; then screw in a corner piece as at O, to strengthen them and hold them perfectly square. These pieces should be about 4 in. long. Now fit another piece between the above to slide up and down in the grooves; this must be about 3 in. long. On this piece mount the lens and mark round the flange; then take it off again, and box it all round close to the mark, as shown at W W, fig. 47, fixing other two pieces on these so that it is closed in. Now below this box screw on the two short racks as fig. 59, and then place the whole in its place in camera and mark the place for pinion, arranging it so that the lens can be both raised and lowered beyond centre of camera. The pinion will work in a slot inside, as it will slide to and fro as the focus is altered, the light being kept out by means of two brass plates on each side, one being slotted and fixed to camera, and the other working behind it, and being fixed to pinion. This looks a trifle complex on paper, but it is really simple enough when on the bench, as you will find who try it. Fig. 61, which is a section through the camera side and plates, will help to make it clear.

FIG. 61.

We have now arrived at the last part of the inside fittings—the shutter. For this make a piece of one-eighth inch board, the full length of the width of camera inside, and about 3 in. wide; this is X in figs. 47 and 60. Fix a rim all round, so as to make a shallow tray about an eighth of an inch deep, bore a hole for lens opening, then make another piece a little more than half the length inside this

FIG. 62.

rim, and the right width so that it will slide to and fro easily; bore a lens hole in this as well, also make two slots about a quarter of an inch from each edge as shown in fig. 60, Y being the sliding piece; screw in the eye as shown, and fix spring, which is clearly explained in drawing. A piece of catgut must be attached to screw eye, and passed through a small hole made for the purpose inside of camera (or rather through the sliding plate Z, fig. 49, which is screwed to frame of shutter, and covers the slot in camera side), and the other end fixed to the movable part of hinge 1, fig. 49. This hinge is also fixed to sliding plate, so that all

moves together when focussing, and the shutter is set by opening hinge, and folding it back towards the front of camera, where it is held by turn-button, a slight push of the latter setting it free and making the exposure. Two small screws must be screwed into X through the slots in Y, to keep the latter in its place. A small bellows body must be fixed to front of shutter frame, so that the front will close up against it and shut out light, and as it is necessary that this should be the case whether the lens is close to front or back as far as it will go, the bellows must be made to spring open. An easy way to effect this is to make a wire frame by winding some spring wire round a square block of the same size as shutter frame, and covering it with black twill; this will always open of its own accord, and yet when needed fold in flat, taking up scarcely any room. If the lens which is to be used has no stops, the shutter can be screwed to the frame W W as shown, but if it has movable stops it must be hinged at the bottom as shown by dotted lines at fig. 48; it will then fold down and leave the lens open for adjustment. The finders can be made next; they will need no further explanation than is given in fig. 62, which is a section, 3 being the lens (any common lens will do), 4 a small piece of silvered glass, and 5 ground-glass. They must be fixed one on each side near the top, the two lens holes show in fig. 54, and the ground-glass opening of one shows in fig. 50, the other of course being on the side for use when the camera is turned side up for vertical pictures. The only fixing they require is a screw through front and top of camera into bottom and back of finder respectively. The front and back of camera can now be made and hinged as shown. The inside of front lid had better be covered with velvet so as to be safe against light entering. It will be noticed that both front and back have a part fixed. The joint must be rabbeted as shown, and the front should have a spring catch, and the back a lock, to insure it against meddling fingers.

The camera is now finished, unless indeed it has to be covered, which is a matter of fancy, and can be done or not. It will make no difference to its utility, though it may make it more of a "detective." We shall also require a handle on top, but neither this nor the covering will prevent any difficulty to the maker, so I will not take up space concerning them.

I hope my instructions have been sufficiently plain for all to understand, and if so, all who have followed them will be in possession of what may I think be called a "universal" camera. I could have made it simpler by using a roll-holder for films, but I do not like this myself, so I would not recommend it to others, not from any particular fault of its own, but it is more costly, and is harder to manage than plates, so I leave it alone and stick to plates, and shall do so, as I think will the great majority.

I gave a list of all the fittings required in Chapter VI, so there is none to give here, but I will just state that a good material for covering can be bought at 2s. per yard, 45 in. wide; and a handle for the top will cost about 1s.

I feel that this is the most difficult looking piece of apparatus I have described so far, and if there is anything I have not made sufficiently plain, I shall be pleased to explain further, if called upon to do so, through the columns of the AMATEUR PHOTOGRAPHER.

## Holiday Resorts and Photographic Haunts.

### A CAMERA TRIP IN THE ROMNEY MARSH.

BY FREDK. GEO. READER.

OF all the sometime seaports which the tide has left high and dry amid smiling meadows and fruitful orchards, the most be-

MERMAID STREET, RYE.

loved of artists is the fine old town of Rye, towering red-roofed over the surrounding marshes, and still having steps leading down to the pleasant gardens replacing the angry grey flood or calm blue sea which once lashed her sturdy sides, or quietly lapped against them, as the case might be.

From any point of view Rye makes a picture. Three rivers flow on three sides of the town, the Rother on the east, the Brede on the south, and the Tillingham on the west, so that it is nearly surrounded by water. The houses rise in three parallel lines of streets, grass-grown, and crossed by lesser streets and lanes, one above another in picturesque confusion, with the massive steeple and low spire of the ancient church, the towers of William d'Ypres and the grey walls crowning the whole site.

As Rye makes a picture whensoever looked upon, so does it afford a view over the curious region of Romney Marsh, extending from Rye to Hythe, and comprising within the great semi-circle of pasture-land (which was once a bay of the sea, which washed the foot of the ridge of hills beyond the canal) the present townlets of old and new Romney and Lydd, as well as the extraordinary promontory called Dungeness.

Excepting Sandwich, Rye is perhaps the quaintest and most picturesque of our ancient sea-towns; and the streets of old Rye are as narrow, as crooked, and quite as irregular as those of the aforesaid Kentish Cinque Port.

Although all views of Rye itself are very good, perhaps the

best is that obtained from a queer little ruin called Camber Castle, which lies about half way between Rye and Winchelsea, built by that much-married monarch "Bluff King Hal," originally for the defence of the coast, but now standing forlorn and purposeless in the midst of the marshes, with the coast line about two miles distant.

Another fine and panoramic view is obtained from the heights leading to Peasmarsh. Rye has suffered by fire on several occasions, and everywhere are the marks left by the flames. Traces of the conflagrations are easily found in the grand old church, said to be the largest parish church in England, and boasting of an Elizabethan clock, also said to be the oldest in England (still going). One cannot but admire the stillness as well as the beauty of this massive edifice. Even the streets of old Rye are marvellously quiet, the stir of business lying nearer to the docks and railway station.

For the amateur photographer in search of the quaint and picturesque, I know of no spot so near London possessing so many attractions as this charming old seaport. There are pretty bits of old-world house building, almost everywhere, round the corners. Mermaid Street particularly contains a charming old house called the "Astrologers' House." Both Mermaid Street and Watch Bell Street are very interesting, and afford a fine view over the marshes.

A few years ago I spent a month at this delightful old seaport, and the weather being favourable, I secured a number of pictures. Although so quaint, it is by no means dull, there is always something to interest. At one time shipbuilding formed a very important and flourishing branch of trade in the port, but of late years it has somewhat declined. The shipbuilders of Rye are still celebrated for modelling fast sailing and smart fishing vessels, a number of which are annually launched.

Of the three "gates" one only remains, the Land-gate, and this stands at the north-east angle of the town.

In the Court Hall are many objects of interest, the remains of the old pillory, the skull of Breede the murderer, and portions of the gibbet chains in which the culprit was hanged, this being, I believe, the last man who wore the chains.

The harbour is formed by a junction of the three rivers, the Rother, the Brede, and the Tillingham, the sea being about two miles from the town. Needless to say that abundance of material is here presented to the picture-maker.

A favourite haunt of mine was at the ferry, and the marshes opposite the ferry. Fishing boats and other craft are always passing up and down the river, and afford good opportunities for shutter work; the town of Rye forming a delightful background. On the opposite height stands Winchelsea, about three miles from Rye. No adjacent towns so similar in position can be so unlike in appearance as Rye and Winchelsea. Here are high grassy acclivities, rising loftily out of the marshes; trees clothe their sides, luxuriant foliage crowns the summit; through the green boughs may be seen, southward, the blue sea with the white-sailed ships; northward the bare lands, laced with a maze of water channels.

Winchelsea was once a fortified town with several gates, of which three remain, the "Pipe Well" or "Ferry Gate," the Strand Gate, and the New Gate. It is now a mere country village, with houses round two sides of the principal quarter, and one small square with a few cottages. Yet how picturesque is the wreck, how venerable are the ruins! One cannot but wonder at this strange desolation.

The chief point of interest at Winchelsea, however, is the church of St. Thomas of Canterbury, of which the chancel with its aisles alone remain. This is very beautiful, early decorated, and may date from about 1300. Near the church are the ruins of the old chapel of the Grey Friars or Franciscan Monastery.

In roaming about Winchelsea one cannot but notice the number of cellars, formerly used for storing the wines of France and the richest wares and merchandise of the Continent. These cellars were once to England what the London Docks are now. They have plain barrel vaults of ragstone, with arched ribs. We descended one of these now used for storing paint. Leading from this were two smaller cellars now used for chopping and storing wood.

A short distance from Winchelsea is the pretty village of Icklesham. The church has a tower with a stunted spire in the centre of the north aisle, and a Norman nave of six bays, and stands among some fine trees, with a large yew on the north

side. Hastings, with its castle and lovely glens, is a paradise for the photographer.

Under the east cliff is found the most picturesque spot. On every side, among a labyrinth of black-timbered store sheds, are strewn anchors and mooring rings red with rust, coils of rope, and heaps of ballast. The boatmen's children play merrily around. Their sturdy fathers, in boots knee high, with striped guernseys or dark blue frocks, are sitting and standing under the lee of their luggers, mending their nets, or tarring their gallant craft. Here indeed are subjects in plenty for the camera or brush.

Pevensey Castle and the village of Westham deserve more than a passing notice; but, having other ground to cover nearer Rye, we must hasten back.

The environs of Rye are rich in subjects for the camera. About half a mile north of Rye is Playden. The church is chiefly Early English. Then about two miles further is a charming village with some of those delightful thatched cottages so abundant in Sussex. In this village lived that loyal gentleman who killed "Jack Cade" near Heathfield, in 1450. Leaving the church on the left, we descend a rather circuitous but pleasant lane to Peasmarch; near the foot of this lane we come to a homely little hostel, "The Hare and Hounds," and since a long walk has lawfully entitled us to a glass of ale and a moderate luncheon, we cannot do better than rest and refresh ourselves here.

Good malt is made in this district, and the two-peaked "oast" house is seen, as in many other Sussex villages. The village of Peasmarch lies some little distance further up the road and is very picturesque. The return journey to Rye can be made across country, passing through several lovely hop-gardens; this is one of the most delightful rambles round Rye.

We will now take a run through that dreary and curious region of Romney Marsh. Intersected by dykes and water-courses, almost treeless, and lying at one uniform level, the region of the Romney marshes is hardly attractive, though the vast plain with its gleaming waterlines has its own beauty, and often presents singular effects of light.

The village of Appledore, once on the verge of the great forest of Andred's Wood, and now forming a hilly island on the Romney Marsh, is prettily situated. The Royal Military Canal passes through this hamlet close to the church. Lydd is nearly four miles from the sea.

The church (of which Cardinal Wolsey was once vicar) is cruciform and has a perpendicular tower.

New Romney and Littlestone-on-Sea are easily reached from Lydd, and are well worth visiting. New Romney, formerly one of the principal Cinque Ports, on the western edge of the marshes, is now but a village without any kind of harbour, and, like most of these ports some distance from the sea, it is a dead-and-alive place, with nothing of interest beyond the church. Formerly there were five churches, of which only one (St. Nicholas) remains. This building is very interesting and has a fine Norman tower, which is one of the land-marks of this remote district.

Romney is mainly celebrated for its sheep fair, it being the metropolis of the Marsh district, which extends from Hythe to Rye. Some curious old customs still exist in the town, one of which is the election of the Mayor in the church.

A short distance from New Romney is Littlestone-on-Sea, a very quiet little watering place with a lifeboat station and a fine open sea. There were at the time of my visit only a few houses, but several in course of building. Littlestone is evidently striving to become a popular seaside resort, and it certainly has some claims, as the air is very bracing and the sands are good, but the country round is awfully desolate.

I would merely add in conclusion, that anyone desiring a quiet rest and thorough change, free from the noisy gaiety of a popular watering place, could not do better than follow the route here briefly sketched out, making either Rye or Winchelsea his headquarters, and if favoured with fine weather and a good pair of legs, can roam with the camera in any direction that his tastes and inclinations may lead him, and be sure of reaping a good harvest of quaint and beautiful pictures.

Fallowfield's "Photographic Remembrancer" for August and September is to hand, containing as usual in its twenty pages a list of useful novelties, one of the most striking of which is "Mezzotype" paper.

## TO ARCADIA WITH A CAMERA.—II.

BY LIEUT. HARVEY.

THE whole of the neighbourhood I am now writing of is, as far as art is concerned, the storehouse of nature, and Fittleworth (the last place to be dealt with in present paper) in particular. To accomplish the exquisite little tour I shall give here, it is necessary that the photographer should have a few days at his disposal, a good stock of plates, and possessing a good pair of legs not afraid to use them, for often after reaching a certain point he must go the rest of the way by the "Marylebone stage,"\* unless he be the possessor of a cycle, or will hire a conveyance—generally in this neighbourhood an extremely old two-wheel cart drawn by a steed the reverse of fiery, broken-spirited, with all the points and angles to be found in Euclid, docile as a lamb, and slow as a tortoise. Apart from these little discomforts, the result will repay a thousandfold any trials and tribulations you may go through prior to reaching the field of extensive operations. It will cost you next to nothing, the innkeepers and country folks here not yet being impregnated with the gold craze and rapid fortunes. Thirty shillings for the week will cover all, unless one is hopelessly extravagant, and even then I doubt whether the resources of the village store would run to the supply of luxurious fare.

To reach this arcadia, book to Steyning (L. B. and S. C. R.), fifty-nine miles from London Bridge. Do not attempt to go and return the same day, for you could never manage it. The result

RYE, FROM THE WATER

would be all hurry, rush, and under-exposed plates. Don't put up at Steyning; good head-quarters can be had further on, and where you will be in the midst of your work. At Steyning you would be seven or eight miles from it. Your road here takes a westerly direction, and you traverse a tract of country remote from railways. Passing through Wiston Park (2½ miles), and Washington Common (4¼ miles), and where you will not then expose a plate unless you arrive early, you reach Storrington (6½ miles), at which place I strongly advise you to make your head-quarters, and can thoroughly recommend the White Horse Inn, where I stayed nearly three weeks, and found clean, cheap, and good plain accommodation. One old man told me that he had never seen a camera until I turned up. During the last five years only three artists have been there, and I strongly suspect they entered into conspiracy, whereby the place has hitherto been sheltered from the rude eyes of the world. It would be utter folly on my part to attempt much description. There is a wealth of beauty, luxurious surroundings, avenues, artistic cottages, glorious views, hills, valleys—in short, all can be summed up in the word of Dominie Sampson, "Prodigious!"

At Fittleworth expose a plate on the church, which stands high. The views from the churchyard are picturesque in the extreme, but from the highest point of Hesworth Common (½ m. W.) there is a superbly majestic scene, and upon which one can well expose half a dozen plates. The whole parish of

\* Or is it "marrowbone stage"?

Fittleworth deserves the profoundest attention of the photographer.

At Storrington there is also plenty of work, though not of such an excellent character as that at Fittleworth.

At Washington Common is Chanctonbury Ring, the "mountains" (814 ft.) On its summit is a well-known circular earthwork, now planted with trees, and commanding extensive and glorious views. Many plates may be exposed in this parish, in which there are many lovely spots. Briefly, if the man who does this trip does not meet with happy surprises on every hand, and visit different spots in this neighbourhood pretty often, then I shall be very much astonished, and shall conclude that I know nothing of art, and had better stick to my "sojering."

### Apparatus.

#### THE IMPERIAL "SPECIAL" LANTERN PLATE.

The Imperial Dry Plate Co., of Cricklewood, London, N.W., have forwarded us a sample of the above lantern plate which they are placing upon the market.

In our hands the plates have given very good results, though we spoiled three before hitting their correct speed, which is greater than any other lantern plate in the market. Notwithstanding the great rapidity, however, the fineness of the image deposit is very good and the gradations satisfactory. The exposure suggested for these plates is about five to ten seconds behind a negative of ordinary density at a distance of 24 in. from a fish-tail burner; and at this distance, with the hydroquinone developer recommended, very rich blacks are obtained. By reducing the distance and the exposure in proportion, and a slight modification of the developer, a very pleasing warm black-brown image was obtained.

The plates yield brilliant slides with good gradation, and good transparency in the shadows, and whilst no one can desire a better plate for contact printing, they will be found of increased value for reducing or enlarging in the camera, from their high sensitiveness.

#### THE IMPERIAL BROMIDE OPALS.

The above firm have also introduced bromide opals which have given also very fine results in our hands. They are of the same rapidity as the lantern plate and are equally suitable for contact printing or enlarging.

We would draw special attention to the prices, which are considerably cheaper than usual, viz., quarter-plates, 1s. 6d.; half-plates, 3s. 8d.; whole-plates, 6s. 6d., etc.

#### THE CROUCH-DRESSER HAND-CAMERA.

Henry Crouch Ltd., of 141, Oxford Street, W., and 66, Barbican, E.C., has placed upon the market a hand-camera specially designed by Mr. A. R. Dresser, one of the most successful of hand-camerists.

It may be obtained either in plain polished walnut wood, or covered with morocco leather, as shown in fig. 1. It is fitted either with a lens working at  $f/5$  or  $f/8$ , of 5 in. equivalent focus, both the lenses being constructed of the Jena glass. The lens is provided with an iris diaphragm, which is actuated from the outside, and the shutter, more about which we shall have to say in another issue, works between the lenses and from 2 sec. to  $\frac{1}{100}$  sec.

A flap falls down at the back of the camera, so that when using the camera on a stand the focussing screen can be used in the ordinary way; and three double dark slides or a roll-holder are provided.

The special feature of the camera, however, is the rising and cross fronts, the action of which is shown in fig. 2, by means of which it is possible to utilise the camera for architectural and ordinary stand work. It is also fitted with two finders and a special focussing lever, and index accurately marked for use when snap-shotting.

We used one of these cameras for nearly a month whilst away for our holidays this summer, and were perfectly satisfied with it.

*Taken with the Crouch-Dresser Hand-Camera on a Barnet extra-rapid plate.*

The lens covers well, the shutter acts with great ease, and, when required, with high and regular speed; and on a run down the Thames on a steamer we did not lose one shot from movement of the object.

The camera is a capable, well made, and efficient instrument, and has given good results in our hands.

#### THE CADETT "LIGHTNING" PLATES.

CADETT is almost a household word in plate making and many friends of the old Cadett plate will be glad to welcome the productions of the new firm, CADETT AND NEAL, OF GREVILLE WORKS, ASHSTEAD, SURREY.

The new "Lightning" plate is, we venture to think, the most rapid yet placed upon the market, registering 59 deg. according to Hurter and Driffield's method, and 88½ by Watkins' method of plate speeds, which are fully borne out by our trials. Combined with this great speed there does not seem to be the slightest lack of density-giving power, nor any want of cleanness of working. For hand-camera work these plates should find special favour. Messrs. Cadett and Neal inform us that they have batches of plates which show 62 deg. by Hurter and Driffield's method, and finally have just attained a sensitiveness of 71 deg., which is equal to 106½ in Watkins' P numbers.

The plates are made in two rapidities, "ordinary" and "lightning," and are sold at what are called popular prices. The firm are issuing also a lantern plate, and propose to place a film upon the market.

## THE VARIOSCOPIIC LENS.

MESSRS. F. DARTON AND Co., of 142, St. John Street, E.C., are placing upon the market Mr. Hugh Blackwood's Varioscopic lens, which consists of an ordinary rectilinear lens with supplementary lenses, both concave and convex, which are fitted near the plane of the diaphragm. It is claimed for this combination that with one rectilinear and the use of certain central lenses plates from  $6\frac{1}{2}$  by  $4\frac{1}{2}$  to 18 by 16 in. are covered. We hope to have an early opportunity of trying this and reporting in these columns. Mr. Hugh Blackwood patented his lens in January, 1889.

## Catalogues.

WILLIAM TYLAR, High Street, Aston, Birmingham. Price 3d.

Tylar's new catalogue makes a brave show with over 100 pages full of the descriptions of the useful and cheap specialities for which he has become so famous. The illustrations in the work show what can be done with his hand-cameras, which are offered in all varieties. Besides his own goods, Mr. Tylar also offers some of the best known apparatus in the market.

WM. HUME, 1, Lothian Street and West College Street, Edinburgh.

This leaflet is a complete price list of all the sizes of Hume's well-known Cantilever enlarging apparatus, which is now made up to eleven inch condensers. We have already spoken highly of this, one of the most useful of all enlarging apparatus.

## Reviews.

*Recepte und Tabellen fur Photographie und Reproductions-technik.* By Dr. J. M. Eder. Third edition. Published by Wilhelm Knapp, Halle a/S. Price 2s.

Collections of photographic formulæ and tables have appeared without number in nearly every language during the past few years, but in this little work of Eder's we really have valuable and useful information collected together which it is difficult to find except by laborious search through numerous works. Not only are recent and reliable formulæ given, but the collection of tables is one of the most complete and useful we have yet seen.

*How to be a Successful Amateur Photographer.* By W. J. Lancaster, F.C.S. Price 1s. Fiftieth thousand.

This little handbook, which is issued by Lancaster and Son, the well-known Birmingham firm, forms a very handy little guide and friend to the beginner, helping him in the choice of apparatus, guiding his footsteps in the proper method of working to obtain successful results, such as shown in the numerous well-printed process blocks with which the work is illustrated.

*Virages et Fixages. Traite Historique, Theorique et Pratique.* By P. Mercier. Published by Gauthier-Villars et fils, Quai des Grands Augustins, 55, Paris. Price 2f. 75c.

In this little volume we have condensed a mass of reliable information on the subject of toning of great value. M. Mercier, who is a chemist of high repute, treats his subject in a masterly manner, and neither the expert nor tyro should be without this, which will become a standard work.

*Annuaire General de la Photographie.* Edited by M. Marc le Roux. Published by E. Plon, Nourrit et Cie., 8, Rue Garanciere, Paris.

This, the first issue of a new Annual, promises very well. It gives a list of the principal clubs and societies of France, with a very good summary of the chief progress in photography during the past year. The illustrations are very good, and form by no means the least attractive part of the work.

*Congres International de Photographie, Bruxelles, 1891.* Published by A. Lefevre, 9, Rue St. Pierre, Brussels.

This volume forms a complete report of the meetings of the International Congress held at Brussels in August of 1891, and contains a list of members, the various addresses given, and papers relating to the subjects on which the Congress deliberated.

## Societies' Meetings.

**Belfast (Y.M.C.A.)**—Usual monthly meeting was held on 12th inst., Mr. J. E. Pim presiding. Arrangements for the winter's work were discussed, and the programme will include short papers and lectures in addition to lantern displays. The prints in August competition were on view. Mr. Meldon, of Dublin, made the awards as follows: J. McCleery, first, with "Early Spring," a study of sheep and lambs, effectively grouped in landscape amid picturesque surroundings. J. A. Pollock, a very close second, with a whole-plate yachting study, entitled "A Good Start," which has just recently carried off the Silver Medal in the AMATEUR PHOTOGRAPHER Monthly Competition. The picture is an admirable one of the forty-tonners starting at the R. U. Y. C. Regatta last July. Alfred George obtained third place with a view of "The Rustic Bridge," Glenariffe, Co. Antrim. The entries for these competitions maintain a very fair average. The new printing frame by Beck was on view, and seems to be a very handy and useful article. One of the Vice-Presidents (Mr. Robert McCann) is proceeding to India at the end of this month, to take up work in connection with the English National Council of British Y.M.C.A.s in the Presidency of Bombay, and would be glad to receive from those who may be interested in the work a number of their surplus lantern slides, for use in that country, and which would be thankfully acknowledged by him if sent to Belfast Y.M.C.A.

**East London**—Ordinary meeting held on the 13th inst., the President (Mr. G. S. Pasco) occupying the chair. The Hon. Secretary distributed sample packets of Paget plates and Ilford P.O.P., which will be reported upon at the next ordinary meeting. Mr. Adams was elected a member. Several negatives and prints were shown by the members. The remainder of the evening was spent in discussing various matters of interest to the society. A musical and social evening will be held, in place of meeting, September 27th.

**Fairfield.**—The ordinary monthly meeting was held on the 13th inst., the chair being taken by the President (Mr. J. L. Mackrell), who, after welcoming the members to the new rooms, proposed a vote of thanks to the various manufacturers who had so kindly sent the fine specimens that decorated the walls. This vote being accorded, he introduced the demonstrator for the evening, Mr. H. B. Sharpe, whose demonstration on "Lantern Slide Making by Reduction in the Camera" proved most interesting, two exposures being made by magnesium ribbon. He also exhibited his new Apus hand-camera together with several other novelties. Sample packets of plates sent by the Paget Prize Plate Company were distributed to members for trial, and report at a subsequent meeting. Arrangements were also come to in connection with the forthcoming lecture of the club.

**Greenock.**—The first monthly meeting of the season was held on the 15th inst. The President (Mr. Jas. Graham) gave an address, and expressed the hope that this would be a successful session. The Secretary exhibited a Bynoe printing frame sent by Messrs. Beck, and also laid on the table copies of *Photographic Work*, the *Photographer*, and a large number of catalogues, pamphlets, etc., sent him. He also stated that the Eastman Co. had some time ago sent sample packets of their new chloride paper, and that he had distributed the packets at the time. The members passed round prints, enlargements, and slides, the work of the summer months. It was agreed to have a lantern slide competition, and two or three lantern entertainments during the winter.

**Hackney.**—On the 13th inst., Mr. W. P. Dando in the chair, Mr

Sodean explained the use of blue glass in the testing of safety of the dark-room light. Messrs. Pollard, Grant, Dean, and Roberts showed work. Mr. Roberts showed some Ilford paper toned with Mr. Welford's bath, and good results were obtained. After a lengthy discussion on the exhibition, it was finally resolved that no member shall be allowed to compete who has not attended meetings at least four times during the last twelve months. Members were advised to send in list of proposed exhibits in order, as they thought best, so that the hanging committee could be guided in selection. Dr. Colquhoun then gave a short demonstration with Amidol. He has used it regularly since August, and was much pleased with it. In cases of under-exposure it was very valuable. Mr. Sodean exhibited a plate he had developed with it. The exposure was  $\frac{1}{8}$  sec. on a London street at f/11 on a dull day, but it had come out very satisfactorily. Dr. Colquhoun then developed some films, using, on the last done, a solution of chloride of aluminium, which he said hardened the film to such an extent that it could be washed in hot water.

**Kendal.**—At the annual meeting held on the 14th inst., Mr. Frank Wilson, J.P., in the chair, the following report was unanimously passed:—The Committee, in presenting their annual report, are again glad to note an increase in the number of members over last year. This is the more pleasing when it is remembered that they have been able to record an increase in the membership each year since the formation of the section. Considerable activity amongst the members has been evidenced during the past summer, many members working really hard and attaining good results. The committee look forward during the coming winter to seeing these results being exhibited in some way, and trust thereby that a still further stimulus may be given to the art-science in this neighbourhood. The committee take this opportunity of impressing on members the importance of securing photographs of old buildings, noted characters, and other similar subjects, which cannot fail to become valuable local treasures in years to come. Many of these have been removed within recent years, and regrets are often and freely expressed that no photograph has been taken. Eleven evening meetings have been held during the year; three of these were devoted to lantern slide exhibition, to which the members of the institution were invited. The committee are glad to think that, evidenced by the large attendance, the meetings were appreciated. The committee again record their thanks to the council of the institution for the use of rooms, and to the proprietors of various papers for the free copies sent for use of members. To the Editor of the AMATEUR PHOTOGRAPHER the committee feel especially grateful for many kindnesses, not the least being the loan of slides and competition prints. The Secretary intimated that, owing to press of other business, he was very reluctantly compelled to decline nomination for the ensuing year. The following officers were then elected: Chairman, Mr. Isaac Braithwaite; Hon. Secretary, Mrs. Frank Wilson; Hon. Treasurer, Mr. F. P. Heath; Committee, Messrs. Frank Wilson, Samuel Rhodes, Charles E. Greenall, and the Secretary of Institution (ex-officio). Considerable satisfaction was expressed that Mr. Paul Lange had kindly consented to adjudicate on the print competition. Messrs. T. Salisbury, J. Dixon, and G. R. Hargreaves, jun., were elected members of the section.

**Lewisham.**—On the 17th inst., Mr. B. Davidson in the chair, Mr. W. C. Chaffey, sen. read a paper on a "Trip to Norway with a Hand-camera," illustrated by lantern slides. The trip was taken with the Polytechnic in the s.s. *Albano*, in June this year. He showed numerous snap-shots of incidents during the voyage, such as Sunday services, deck billiards, and quoits (one slide showed the quoit in mid-air), leap frog, passengers overcome by mal-de-mer, etc. The first port of call was Stavanger, from whence the ship worked in and out the numerous fiords to Trondhjem, coming back again to Haugesund. Fortunately, Mr. Chaffey took his ordinary besides his hand camera, as the inland scenery wanted long exposures in very many cases, besides needing lenses of various foci.

**Liverpool (Camera Club).**—The usual meeting was held on the 14th inst., under the presidency of Dr. Webb. After the usual preliminaries had been gone through, the Chairman called upon Mr. W. A. Stuart to give his paper on the "Paget Prize Plate Exposure." Mr. Stuart, at a deal of trouble, had tabulated the various exposures, with the light, stop, and exposure given. Mr. Stuart went through this table, and, in an interesting manner criticised each exposure and the results, which on the whole were very satisfactory, though the exposure in some cases varied 100 per cent. The conclusion to be drawn from this, Mr. Stuart stated, was that with the class of plates now made a great amount of latitude is permissible in exposing, if a little care is displayed in development. A general discussion then took place upon the foregoing, and the consensus of opinion was that, to have a real test, the development should be described as well as the exposure, etc. It is proposed to have a club smoking concert on October 12th.

**London and Provincial.**—A meeting was held on the 15th inst., Mr. E. J. Wall in the chair, Mr. E. H. Fitch was proposed as a member. Messrs. Beck's "Bynoe" printing frame was handed

round for examination. A letter was read from the Photographic Society of Great Britain stating that members of the Association being affiliated to the parent Society could purchase tickets for the exhibition at half price. The following question was found in the question box: Whether a bath composed of hypo 4 oz., nitrate of lead 30 gr., alum 2 oz., phosphate of soda 10 gr., and water 10 oz., would give permanent prints. Messrs. Haddon, Everitt, and Bolas took part in the discussion, and it was generally considered that prints toned in such a bath would not be permanent. The Chairman then introduced Dr. C. L. Mitchell, of Philadelphia, to the meeting, who then gave a brief address upon the printing methods and plates most used in America. Numerous questions were asked by the members, and answered by Dr. Mitchell, and after some further discussion the meeting closed.

**Newcastle.**—On the 15th inst. the last out-door meeting of the season was held. The party, driving in brakes from Gilsland, visited Bird-Oswald, Coom Craig, Lanercost Priory, and Naworth Castle. The weather was favourable, and a very enjoyable day resulted. Mr. M. Auty acted as leader in his usual thorough manner.

**Putney.**—Members met on Wimbledon Common on 17th inst., and were favoured with the most lovely weather. Successful negatives were taken of the firing parties at the various ranges, as well as of the golfers, who frequent this fine common in large numbers, and whose characteristic attitudes form excellent subjects for snap shots. At the invitation of Mr. Faulkner, member of Council, the party proceeded to his house at Roehampton, where they were hospitably entertained. The remainder of the afternoon was spent in photographing in the picturesque grounds and fine palm houses, in which latter may be seen some of the most perfect specimens in this country of several kinds of palms, ferns, and mosses. This was the last of the summer outings of the present season, and a worthy finish to the series. The winter season opens on Monday, October 10th, when a social meeting will be held in the rooms of the Society, in the Charlwood Road, at 8 p.m.

**Sheffield (Optical Lantern).**—The usual monthly meeting was held on the 15th inst., Mr. J. T. Frith, Vice-President, occupying the chair. Objects of interest were handed round, including a new form of photo-micrography, after which Dr. Manton delivered his unique little lecture, entitled "Pictures of Dutch Life," illustrated by lime-light views taken by him during a recent continental holiday. The pictures, numbering between forty and fifty, make a very complete set illustrative of the different phases of life in the Netherlands. The lecture, which was both interesting and instructive, was listened to by a large number of members and friends.

**Sutton.**—The forty-first meeting was held on the 5th inst., Mr. De Clifford being in the chair. Trial plates, sent by the Paget Company, were distributed among the working members, and a competition arranged for negatives and prints taken by these plates to be exhibited at the next meeting. An enlarged framed picture of instantaneous groups, taken by these plates and sent by the above company for hanging in the room, was shown and much appreciated. A discussion afterwards took place on development, Mr. De Clifford being strongly in favour of amidol, results under his hands proving exceedingly good.

## To Correspondents.

All communications for these columns are to be addressed to **The Editor, "Amateur Photographer," 1, Creed Lane, Ludgate Hill, London, E.C.**

### RULES.

1. Write clearly and distinctly on one side of the paper only.
2. Write each Query or Answer on a separate sheet of paper.
3. Write the name and address legibly on the back of each communication, and sign all Queries and Answers with name or *nom de plume*.
4. All matters for these columns MUST be received by **TUESDAY MORNING'S POST**.
5. The Editor does not undertake to answer questions by post.
6. In answering Queries, correspondents are requested to mention, in every instance the number and full title of the query referred to.

## QUERIES.

5817. **Platinum Printing.**—Will some of the numerous readers of this paper kindly tell an ignorant one what is the best and simplest platino-type paper to work, and where I can obtain it? Cold-bath preferred.—**HARRY.**
5818. **Hymn Slides.**—Will anyone tell me how to make a slide with a hymn on it? I have an amateur's camera, but I find when I take a photograph of a small or ordinary print, it is smaller still. How shall I be able to make one with the nice-sized print generally on slides? A lucid explanation will be highly esteemed.—**PUZZLED.**
5819. **Seaside Exposures.**—Will someone kindly let me know whether seascapes require longer or shorter exposure than others? Staying at the seaside I took some photographs on the same kind of plates (Ilford rapid) and same exposure and same light, but all the sea views were very thin negatives, while the portraits, groups, and houses and other views came out good negatives full of detail.—**ARISTOTLE.**
5820. **Blackening Stops.**—I should feel obliged by someone kindly telling me if Aspinall's black enamel would do to black stops with, as the tin division in my dark-slides is evidently painted with enamel, and I have had no bad results from them?—**ROY.**

Correspondents not seeing their queries inserted are requested to look for the same under "Editorial."

## QUERIES UNANSWERED.

- Sept. 2nd.—No. 5801.  
 " 9th.—Nos. 5807, 5808.  
 " 16th.—Nos. 5813, 5814, 5815, 5816.

## ANSWERS.

5812. **Lantern Screens.**—I have used a transparent screen of tracing linen for a 3 ft. disc, and it answers fairly well. Lately I have been using a 6 ft. transparent screen made of muslin for outdoor lantern work, and I am inclined to think it is the best material of the two for the purpose.—**ALFRED WATKINS.**

## EDITORIAL.

**SPECIAL NOTICE.**—We are very pleased to find that replies in this column are so much appreciated, but we should be very grateful if those requiring advice would send their letters to us BEFORE **TUESDAY MORNING'S POST** if possible. The time occupied in replying in this column is very considerable, and owing to the often late receipt of letters, many matters have to be left over each week. This we much regret.—**ED. AM. PHOT.**

**CARRY.**—Your queries are of such a nature as to be inadmissible in our columns, and were unfortunately overlooked last week. You will have seen our report of the camera named in your letter in our issue of last week, and further use of it only confirms our good opinion of it. It is simplicity itself. Of the three lenses you name there is nothing to choose between them; they are all of the same rapidity. Portrait lenses are certainly superior to rapid rectilinear lenses for portraiture; next to the portrait lens comes, as a makeshift, the single landscape lens working at an aperture of  $f/8$ . The R.R. lenses working at  $f/5$  are, however, to be preferred to the single lenses, but are not so good as portrait lenses. If you will use the following solution for your glasses you will find no difficulty in stripping your prints.

Yellow wax .. .. .	24 gr.
Yellow resin .. .. .	12 "
Benzole .. .. .	2 oz.

It is possible to enlarge with any lens which is used for taking negatives, and therefore your 7 in. Beck may be used.

**CARAPACHAY** (Buenos Ayres).—Mr. Henry Park, of 5, Station Buildings, Acton Street, Kingsland, London, N., quotes for quarter-plate camera, as per Major Bruno's articles, 45s., and for 5 by 4, 50s.; this is without lens, shutter, dark slides, and finder.

**F. B. JONES** (Ontario).—Jabez Hughes' "Principles of Wet Plate Photography," can be obtained from J. Werge, 11a, Berners Street, London, W. Snowden Ward has also written a little work called "The Practical Ferrotypist," price 6d., which may be had from Percy Lund and Co., Bradford.

**W. G. GROVES.**—We have not the slightest objection to whites or high lights, but the eye can see detail in these high lights which are too often lost in the prints, and we certainly think that one or two of your prints were too hard in the lights. We remember specially some white blouses which were far too devoid of detail. Can you not call and see us and bring some prints up, and we can talk the matter over?

**H. P. B.**—B camera most certainly. The films may be used to enlarge from direct; all that is required is something to hold them flat. Scanlan's film-holder is the best for this purpose, to be obtained from England Brothers, 21, Charles Street, Notting Hill, W.

**J. S. T.**—Write to Davenport and Co., 32, Parkhouse Street, Camberwell, S.E., who will do all you want, even if they have nothing in stock to suit you.

**G. HARVEST.**—Many thanks for your notes.  
**F. E. C.**—The films you name are not quite so rapid as the special plates; they can be developed with hydroquinone. See our note on Cadett's lightning plates this week; we believe they are the most rapid yet on the market.

**S. C. L.**—We shall be glad to do all we can to help you. We can lend you about 300 slides in all. Let us have a letter for publication on the subject, and we will make a note of it.

**G. T. WOODLEY** and **J. W. WRIGHT.**—The fault was partly ours; let us know what particular cuts you refer to, and we will specially mark them and forward.

**O. N. F. KELLY.**—Your fault lies, we think, in the plates you are using. For such work as you require, you must have a pure bromide or slow bromo-iodide plate; not a chloro-bromide, like the one you now use. We should advise you to obtain some of Mawson and Swan's photo-mechanical plates, and reduce your exposure slightly, not much, but we think Watkins' estimates are rather too long for copying. If you obtain the photo-mechanical plates you can use either a hydroquinone or pyro developer. We should use the pyro, but if you prefer hydroquinone, stick to it.

Hydroquinone .. .. .	80 gr.
Metabisulphite of potash .. .. .	120 "
Bromide of potash .. .. .	5 "
Distilled water .. .. .	20 oz.

II.  
 Caustic potash, pure .. .. . 200 gr.  
 Distilled water .. .. . 20 oz.

For a normal exposure mix in equal parts.  
**Stock Pyro Solution.**  
 Metabisulphite of potash .. .. . 1 oz.  
 Bromide of potash .. .. . 640 gr.  
 Distilled water .. .. . 8 oz.

Dissolve, then add 1 oz. of pyro, and make up to 10 oz.  
**Developer No. 1.**  
 Stock pyro .. .. . 2 oz.  
 Water .. .. . 18 oz.

**Developer No. 2.**  
 Liq. ammonia .SSO .. .. . 1 oz.  
 Water .. .. . 19 "

For normal exposure mix in equal parts.  
**Stock Sol. Pyro.**  
 Metabisulphite of potash .. .. . 2 oz.  
 Bromide of potash .. .. . 240 gr.  
 Water .. .. . 8 oz.

Dissolve, and add 1 oz. of pyro, and make up to 10 oz.  
**Developer No. 1.**  
 Stock pyro .. .. . 2 oz.  
 Water .. .. . 18 oz.

**Developer No. 2.**  
 Saturated solution of washing soda.

For normal exposure, mix in equal parts. If you cannot obtain Mawson plates try Edwards' special transparency plates, which have given equally as good results in our hands. Possibly you had better use the hydroquinone, as it is somewhat easier to use, but you must carry development as far as you can without blocking of fine lines. Sometimes it is absolutely impossible to obtain clear lines and sufficient density, in which case the latter is sacrificed, and intensification resorted to. Will you try, and then let us know again. (2) We have been using the Imperial with very fine results; possibly there is no best.

**V. W. M.**—The prints received for competition are loaned to societies, the members of which, from all accounts, much enjoy looking through them. We retain the prize pictures in order that we may use them for reproduction in a permanent form at the end of the year. It was our custom to print all the details, but as this was suggested to us as being unfair to some makers of plates, etc., we now omit it. Actually there is not much in the particular plate or

camera; it is the man who stands behind who works for and gets the medal.

**AUSTRAL.**—The only remedies we can suggest are the well-known one of weak solution (about 5 grs. to the oz.) of cyanide of potash.

**D. W. F. M.**—(1) A good subject, and well taken, but spoilt by printing in the sun. (2) The foreground of this wants shading during printing, and it could be improved by some clouds. (3) Utterly spoilt by printing in the sun. (4) Cut off an inch and a half of the uninteresting foreground. All your prints are spoilt by printing in the sun; but for this they would be up to competition standard. Let us see some more work that has not been thus treated.

**A. H. DUNCAN.**—Thanks for your letter. Try again and see if you cannot come out higher still. You were not awarded a certificate, though the judges pressed us hard to award some more, but we do not want to make them too cheap.

**F. G. LLOYD.**—Grams is a mistake; it should be grains. Thanks for pointing out the error.

**A NEW A. P.**—We will send you on pulls of blocks with lettering distinct.

**A. CARTER.**—The one great fault in your print is hardness; the whites are too white. You will find in our issues of this month a paper by J. McIntosh on "Harmonising Harsh Negatives," which would help you to reduce contrast. But for this hardness the print is a good one, but would have been far better if taken in the shade.

**TYRO.**—There are no patent rights about a pinhole, although a special form of plate with different apertures is patented. Will you write us in confidence, and let us know your idea, and we may be able to help you.

**BOTANY BAY.**—The only competitions likely to suit you are our monthly ones.

**R. B. WORTH.**—Your negative was received broken into two pieces. The usual explanation of these holes or pinholes as they are called is dust on the plate. Before placing the plate in the dish pass a clean soft handkerchief carefully over the surface, and when in the developer rub your fingers, which must be clean, all over the plate. Do you want negative block?

**A. HAIGH.**—You can obtain the biconcave lenses from C. C. Vever's, of Market Street, Briggate, Leeds, mounted in wood at 9d. each.

**TRIX.**—We shall be very glad to have a note on Ely Cathedral for our Annual next year. (1) There is no class below No. 4. All the prints not included in Classes 1, 2, and 3 go in Class 4. (2) The last volume, vol. 15, began Jan. 1st, 1892, and ended June 24th. (3) Rather thin negatives are most suitable for bromide printing, and about 10 secs. will be enough at 18 in.

**CATTON.**—The best thing you can do is to make a V-shaped trough with a very narrow slit running all along the apex, and, filling the trough with the solution, draw it over the paper, or the paper under it, and thus coat it. If you cannot understand, we will forward you sketch on receipt of stamped envelope.

**J. P. B.**—Your print is rather flat; either the negative is thin and wants intensifying, or else you have been printing in too strong a light. The lines of the tree masses converge too much to the centre, and the figures do not improve it. It is, however, superior to many we get in the competitions.

**H. S. P.**—(1) Decidedly good, but as you say, printed too dark. (2) A little too hard, the walls of the cottages are too white. (3) The left-hand side of the print shifted, we should say, in the printing-frame—as a whole it is wanting in interest. (4) Overprinted, otherwise a very nice little study. (5) The pink tinge is due to the action of the borax bath which too frequently gives this tinge to chloride papers. (5a) Over-printed and over-toned. (6) Good, though a little too hard.

**RUEYAMA.**—All your slides are slightly over-exposed, and the boats and sheep want clouds to complete the pictures. If you make better slides, they will probably stand a chance.

## Sale and Exchange.

### RULES.

**CHARGE.**—Twelve words or less for Fourpence. Every additional three words, one penny. The name and address of the sender must be paid for. (A single figure, or group of figures undivided by letter, space, stop, or words, counts as one word; compound words count as two words.)

**DEPOSITS.**—The money for goods forwarded on approval may be deposited with the Publishers of the **AMATEUR PHOTOGRAPHER**, who will hold the amounts deposited until they are satisfied that the transaction has been completed to the satisfaction of buyer and seller.

**ADDRESS.**—All advertisements (which can be received up to **Tuesday mid-day**) and other communications having reference to the "Sale and Exchange" column, must be addressed "Sale and Exchange, **AMATEUR PHOTOGRAPHER**, 1, Creed Lane, London, E.C."

**COMMISSION.**—A charge of 2½ per cent. will be deducted from all deposits whether a sale is effected or not. Minimum charge 1s.

**PAYMENT.**—All payments are to be by cheques of Postal Orders, made payable to **Hazell, Watson, and Viney, Ltd., 1, Creed Lane, London, E.C.**

**CARRIAGE** must be paid on all apparatus sent for report, and they will be returned carriage forward.

**ADVERTISEMENTS** can be inserted under a number the name and address being registered, and letters forwarded for a fee of 3d. to cover postage.

**PAYMENTS** should be made in Postal Orders or Postage Stamps.

**REPORTING.**—Apparatus may be sent to the **EDITOR, AMATEUR PHOTOGRAPHER, 1, Creed Lane, London, E.C.,** who will report upon the apparatus to the buyer for a minimum fee of 2s. 6d., or a commission of 2½ per cent., upon the sale price of the apparatus.

**Background.**—Two beautiful backgrounds, 8 by 6, on rollers, interior and exterior, by Redshaw, new, also wall background box for same, very handy for outdoor purposes, accept £2 10s., half cost.—Joseph Smith, Strawberry Bank, Blackburn.

**Cameras, etc.**—Half-plate camera (Fallowfield), all movements, Eastman rollholder, and three slides, 5 guineas; approval; deposit.—Broomhall, St. Margaret's, Twickenham.

Whole-plate mahogany camera, square bellows, reversing back, two double dark slides, first P.O. 15s. has it.—James, 9, Bessborough Road, Ilford, Essex.

Half-plate Lancaster's 1891 Instantograph, no lens, three double box slides, Lancaster's pneumatic Seasaw shutter, four-fold Cyclist stand, bought last October, hardly soiled, only used a few times, £4 10s. F. J. Thomas, 70, High Street, Deptford, London, S.E.

For sale, half plate Lancaster's Le Meretore, slide, tripod, quarter-plate carrier, no lens, good as new, 28s.; approval; deposit.—Crozier, Hexham.

**Dark-room Tent.**—Portable photographic dark-room tent, splendid condition, price £3 10s., cost over £7.—Grant, Aldwick Place, Bognor, Sussex.

**Enlarging Apparatus.**—Lancaster's enlarging camera, 12 by 10, without lens, also dishes.—A. J. Norrington, Purley, Surrey.

**Hand-Cameras, etc.**—5 by 4 Kodak, equal to new, 30 films, fitted to hold 100, a bargain, £6 5s.—264, Hainton Street.

Folding Kodak No. 4, splendid condition, price £7 10s.; also portable dark tent, very complete, window shelves, etc., good condition, cheap, 30s.—Higson, Falmouth Hotel, Falmouth.

Kodak, No. 3 Junior, perfect condition, £6.—Spurrell, 6, Tavistock Place, Plymouth.

B Daylight Kodak and roll of film, cost £3 5s., price £2 10s.—Tonkin, 22, Market Place, Penzance.

For sale, No. 1 size Kodak camera, with view finder, full spool of the new transparent films, cost £5 5s., price £3 10s.—W. C. Callender, Bonnington Tannery, Leith.

Miller's Adelphi quarter-plate, with 12 sheaths, Optimus R.R. lens, Thornton-Pickard shutter, sunk finder and tripod, £4 10s., a genuine bargain.—P. Saunders, 17, Ash Leigh, Anfield, Liverpool.

Kodak, No. 3 Junior, 50 films, unexposed, equal new, cost, with special case, £8 15s., price £6 5s.—B., 13, Canterbury Road, Brixton, S.W.

**Lenses, etc.**—Rapid rectilinear! French make, special value, 5 by 4 ½ in. focus, 11s. 6d.; 7 by 5, 7 ½ in. focus, 14s.; 9 by 7, 11 in. focus, 20s., complete with hood, flange, cap, and set of Waterhouse stops largest aperture f/8; three days trial allowed.—Dorey, Lester and Co., Kilburn, London.

Crouch half-plate rapid landscape lens, Thornton-Pickard shutter, 30s., cost 48s. 6d.—Bartlett, 3, Anslies Belvedere, Bath.

**Print Washer, etc.**—Jefferies' Patent Perfect washer, as new, cost 16s., will take 10s.; also Marion's United rectilinear half-plate lens (21s. 6d.) for 15s.—No. 335, office of this paper, 1, Creed Lane, E.C.

**Rollholder.**—For sale, Eastman rollholder, half-plate, quite new, 30s.—No. 334, office of this paper, 1, Creed Lane, E.C.

**Sets.**—Exchange Lancaster's quarter-plate camera, Ross' lens, two double slides, tripod. Wanted, 10 by 8 combination Miltum-in-Parvo.—J. Green, Palfrey, Walsall.

Lancaster's half-plate International camera, Silver Ring R.R. lens, iris diaphragms, three Lancaster's double slides and three Tylar's metal, four-fold tripod, solid leather, baize-lined case, Optimus finder, focussing cloth, etc., in excellent condition, thoroughly sound, no approval, only wants seeing, cost over 10 guineas, cash £7.—Thomas, "Lanteglos," Globe Avenue, Enfield.

Quarter-plate camera complete, consisting of tripod lens, shutter, and case; also three dishes, two printing frames, and ruby lamp, cheap.—A. Partington, Molyneux Street, Longsight.

Underwood's Instanto half-plate camera, Ashford stand, five double slides, R.R. and W.A. lens, and complete apparatus for turning out photographs, £8; worth double.—Davies, 22, Market Square, Pontypridd.

Complete set, including Lancaster's quarter-plate camera, tripod, lens, two double slides, focussing cloth, and sundries, in case, 28s., original cost 55s.; Lancaster's portrait lens, quarter-plate, cost 21s., take 15s., or 40s. the lot.—Glover, Percy Villa, Warwick.

Whole-plate sliding body portrait camera and good lens (Marion and Co.'s), with strong studio stand, the lot £4, or sell separate, or make useful exchange; also half-plate bellows camera, lens, two backs, and tripod, complete, £3.—Chave, 30, Marine Parade, Worthing.

Lancaster's 1891 Instantograph camera, lens, dark slide tripod, and view finder tripod, new a month ago, price 25s.—Apply, M., 15, Endsleigh Gardens, London, N.W.

**Bargain!** International quarter camera, R.R. and W.A. lens, Thornton-Pickard shutter, time and instantaneous, six double backs, and complete apparatus for turning out photos, take £3, cost double, or exchange good half-plate camera.—D. Travis, St. John's Road, Fazakerley, Liverpool.

**Shutter.**—Kershaw's instantaneous shutter, 1½ hood, as new, 8s. 6d.—A. L. Spiller, Hillside, Hampstead Hill Gardens, London.

**Sundries.**—207 consecutive numbers of **AMATEUR PHOTOGRAPHER**, clean, no reasonable offer refused.—George Howard, Boston Grove, Rotherham.

## WANTED.

**Lenses, etc.**—Wanted, whole-plate rectilinear lens, for violin, bow, case, and cash.—Sansome, South Beach, Blackpool.

**Sets.**—Wanted, modern double extension half-plate camera and three double backs, brass bound, with rapid rectilinear lens and stand, all by first-class maker; also camera case and time and instantaneous shutter; must be in excellent condition. Particulars to D. Little Berkhamstead House, Hertford.

**Shutter.**—Wanted, Chronolux or other time shutter to fit 3½ in. lens.—H., 36, Spencer Square, Ramsgate.

## Bargains in Hand Cameras.

—Kodak, No. 4, size 5 by 4, new spool of films, warranted finest condition, in leather case, take £7 17s. 6d., cost £11 7s. 6d.; Adams' Ideal hand-camera, twelve quarter-plates, finest rapid rectilinear lens, time and instantaneous shutter, as new, £5 15s.; Fallowfield's Facile, fitted rapid rectilinear lens, carries twelve quarter-plates, as new, £3 17s. 6d.

Optimus magazine hand-camera, covered leather, carries 12 quarter-plates, finest Optimus rapid rectilinear lens, two finders, shutter, etc., as new, take £5 5s.; Talmer hand-camera, carries 12 plates, fine lens, two large finders, time and instantaneous shutters, as new, take 65s.; Steinheil hand-camera, 9 by 12 centimetres, rapid rectilinear lens, two finders, shutters, carries twelve plates, bag changing, as new, take £4 10s., cost £10 10s.; Samuel's quarter-plate hand-camera for twelve plates, quite new, rapid rectilinear lens, two finders, take 27s. 6d.; Griffiths' best quality hand-camera, carries six ½-plates, two sunk finders, good lens, pneumatic shutter, take 30s., cost 42s.; quite new, all above are warranted as described. On view, City Sale and Exchange Rooms, 54, Lime Street, corner of Leadenhall Street, City (late Goy's Medium).

Second hand apparatus bought, sold, or taken in exchange. Inspection invited.

**Cameras! Cameras! Cameras! Lenses! Lenses! Lenses!** and photographic apparatus of every description.—We are agents for all the first-class makers and can supply any set upon the best possible terms, either for cash, by easy payments, or by exchange. Every description of apparatus taken as part payment for new. Cameras and sets lent on hire, by the day, week, or month. Lists free by post. Prompt attention, best discounts, approval by arrangement, and a guarantee given with every article to be genuine in every detail.—City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus of every description bought, sold, or taken in exchange. Inspection invited.

**Bargains in Lenses.**—15 by 12 rapid rectigraph lens, Silver Ring, iris stops, grand definition, take £5 17s. 6d., quite new; whole-plate Voightlander's rapid rectilinear, fine definition, best order, 90s.; whole-plate Optimus rapid landscape lens, quite new, rotating stops, 35s.; whole-plate Lancaster wide-angle lens, rotating stops, 15s.; 8½ by 6½ Ross rapid symmetrical, Waterhouse stops, grand definition, as new, £4 10s.; Wray's 7½ by 5 wide-angle rectilinear, rotating stops, as new, 47s. 6d.; half-plate aluminium rapid rectilinear, by Parkes, Waterhouse stops, 30s.; half-plate Ross' portable symmetrical, rotating stops, 4 in. focus, finest order, 45s.; half-plate wide-angle, by Morley and Cooper, rotating stops, as new, 27s. 6d.; half-plate Ross' rapid symmetrical lens, as new, moveable hood, Waterhouse stops, take £3 17s. 6d.; Wray's landscape, Caskeet lenses, 5 in., 7½ in., and 10 in. focus, iris stops, quite new, take 70s.; Ross' c. d. v. portrait lens, rack and pinion, finest condition, 35s.; Shew's c. d. v. portrait lens, Waterhouse stops, rack and pinion, as new, take 21s.; Optimus 5 by 4 rapid Eury scope lens, by Perken, Son, and Rayment, Waterhouse stops, as new, 47s. 6d.;

quarter-plate Optimus rapid rectilinear, by Perken, Son, and Rayment, Waterhouse stops, covers 5 by 4, focus 5½ in., quite new, take 27s. lowest. All above lenses are warranted as described.—On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Every description of apparatus bought, sold, or taken in exchange.

## Bargains in Cameras and Sets.

—12 by 10 camera, double extension leather bellows, wide-angle movement, double dark slide, fitted fine rapid rectilinear lens and sliding stand, a grand lot, £9 17s. 6d.; Optimus whole-plate camera, leather bellows, reversing back, etc., Optimus 9 by 7 rapid rectilinear lens, Waterhouse stops, Thornton-Pickard shutter, three double dark slides, three-fold stand and case, £11 5s.; whole-plate Underwood Instanto, wide-angle movement, leather bellows, double extension, rapid rectilinear lens, iris stops, fine definition, double slide, half-plate carrier and folding stand, as new, take £5 15s.; whole-plate camera by Hare, grand article, leather bellows, double extension, wide-angle movement, double slide ~ changing box, for 24 plates, all changing slide, Optimus rapid rectilinear lens, Waterhouse stops, brand new three-fold stand and case, take £10 17s. 6d.; 7½ by 5 long-focus camera, by Gotz, wide-angle movement, leather bellows, reversing back, rapid rectilinear lens, and folding stand, set complete, £5 15s.; half-plate Underwood's Instanto wide-angle movement, double extension, fitted rapid rectilinear lens, slide, and folding stand, £3 17s. 6d.;

half-plate camera, by Houghton, all latest improvements, Instantograph lens, iris stops, shutter, double slide, folding stand and case, take 72s. 6d., as new; Optimus half-plate camera, guaranteed as new, all improvements, three double dark slides, rapid rectilinear lens for views or portraits, three-fold stand and case, take £6 10s.; quarter-plate Lancaster's Merveilleux set complete, 15s.; Lancaster's Convention set complete, camera, lens, shutter, slide, and stand, as new, 40s.; quarter-plate aluminium Instantograph set complete, quite new, camera, lens, slide, shutter, and stand, 50s.; quarter-plate Instantograph camera, lens, shutter, slides, and folding stand, 32s. 6d. All above guaranteed finest order.

On view, City Sale and Exchange Rooms, 54, Lime Street, corner Leadenhall Street, City (late Goy's Medium). Second-hand apparatus bought, sold, or taken in exchange. Inspection invited.

It is unnecessary to send an advertisement for the "Sale and Exchange" column for more than one insertion, as the goods are usually disposed of when the first advertisement has appeared.

**AMATEURS**, have your Negatives artistically Retouched. Cartes from 3d., cabinets from 4d.—Stickell's, Midhurst, Sussex.

**J. LEIGH**, Wardleworth, Artist (Painting and Photography). Copying, Developing, Printing, Enlarging, Portrait Painting, Prompt attention, moderate terms.—High Bank Terrace, Heaton Park, Manchester.

**IMPORTANT TO AMATEURS.**—Negatives skillfully Retouched. Printed in silver, gelatin-chloride, etc., and Enlarged. Also Developing, Copying, etc.—Terms strictly moderate.—Address, Wilfred Emery, 24, South Street, Baker Street, W.

**ENLARGING APPARATUS.**—Hume's enlarging apparatus, 5 in. condenser, without objective, 61s. 6d.; with 8 in. condenser, 122s. 6d., carriage paid.—Hume, 1, West College Street, Edinburgh.

**THE BOOK OF THE LANTERN.**

By T. C. HEPWORTH, F.C.S.

A Practical Guide to the Working of the Optical (or Magic) Lantern—either as an Educational Instrument, for Exhibition Purposes, or as an Enlarging Apparatus for Photographers. With full and precise Directions for Making and Colouring Lantern Pictures. Price 3s. 6d., post free.

"Here we have something like a lantern manual! A handsomely bound, comprehensive work, written by an acknowledged master in lantern operations."—*Photographic News*.

"Comprehensive, and is characterised by an excellent literary style."—*British Journal of Photography*.

"It is without exception the best book that has been published."—*The Amateur Photographer*.

Entry forms, etc., on receipt of stamped envelope. Address: Editor, AMATEUR PHOTOGRAPHER, 1, Creed Lane, E.C. (Prizes will be announced and photographs reproduced and criticised in the AMATEUR PHOTOGRAPHER Supplement, November 11th.)

THE suspense of the last month or two is over. The Pall Mall Show is opened, and the result is not general desolation, and a sense of defeat, as was predicted by some. It has been anticipated ever since the fracas of last year that the abstention of some notable workers was inevitable, and prophecies that the wreck or ruck left behind would be lamentable in the extreme were by no means wanting.

BUT unfortunately, with great fear and trembling at their own audacity, the Council of the Photographic Society of Great Britain did their best, and the result has been—what?—nothing but undoubted success. The "morituri to salutant" has been changed into a pæan of triumph.

WE heartily congratulate the Council on the exhibition, and the Hanging Committee on the courage with which they have exercised their rights, as it is an open secret that whereas there are 648 exhibits, exclusive of apparatus, no less than 240 pictures were rejected. Practically we may consider that this "wreck" of a show is one of the most successful which has been held for several years, both as regards numbers and quality.

IT was almost ludicrous to hear on every side at the conversazione, "Well, what do you think of the show?" or, "This is the wreck, is it?" "Certainly the best exhibition held for the last few years;" and this last is our opinion. One particularly noticeable feature is the absence of bad work. The general run of the work is certainly high, although there is no picture which may be called "the picture of the exhibition."

THE Times, which is supposed to rank as the leading newspaper, has naturally reviewed the Pall Mall show, and says:

"For some time rumours have been rife that, in the opinion of many, the society has ceased to fulfil its representative functions in such a manner as to give general satisfaction to the numerous interests with which it is connected, and it would appear that the dissatisfaction expressed has so far taken a practical form as to lead to the abstention of a considerable number of those who have in former years been prominent exhibitors. That abstentions so numerous and of such representative men could scarcely fail to have a marked effect on the general quality of the exhibits, and consequently on the success of the exhibition, need not be said.... The leading points of interest in the exhibition lose, no doubt, considerably from the abstentions to which we have already alluded—abstentions which, among other things, leave almost unrepresented a class of work which has of late years come to the front—we mean

that in which the higher forms of art are applied to photography. Under such circumstances it is difficult to award unqualified praise.

—♦♦♦—

It is interesting to note the different view here given of the fracas of last year, to that usually accepted. Fourteen exhibitors' work only is mentioned, and some of this is damned with faint praise; but possibly an explanation is to be found in the report that the critique was written by Mr. Maskell, who is one "of a considerable number of those who have in former years been prominent exhibitors," but who this year abstains from showing work. The whole article conveys the idea of a covert sneer unworthy of the columns of the paper in which it appears.

—♦♦♦—

"Photographs of the Year," will, we think, be fully equal this year to that of last. The selection of the pictures was placed in the hands of Mr. A. Horsley Hinton, so well known for his artistic work and writing, and up to the moment of going to press we have received permission to reproduce the following pictures by the following gentlemen:—

"Quiet Life." By Karl Greger.

"The Silver Strand." By Gay Wilkinson.

"Flatford Bridge." By Col. J. Gale.

"The Foot Bridge." By F. P. Cembrano, jun.

"The Love Letter." By A. Burchett.

"Portinscale Bridge, Keswick." By T. M. Brownrigg.

"A Sluggish River, Choked by Sedge and Flag." By George Lamley.

As the edition will be limited, we would ask our readers to immediately send their orders to our publishers, an order form for which purpose will be found on p. v.

—♦♦♦—

THE veteran journalist so well known by his initials G. A. S., gives the following explanation of a fact we have often wondered at, namely, the congregation of professional photographers in Regent Street:—

"I have always thought it to be entirely within the fitness of things that photographers should abound in Regent Street. Ever so many years ago, far down the street, on the east side, was the Daguerreotype Gallery of M. Claudet, a worthy old French gentleman, who flourished as late as the Paris Exhibition of 1867; and in the window of an optician's shop on the west side, close to where is now the establishment of the London Stereoscopic Company, I saw the first photograph on paper that ever greeted my eyes. It was a transcript of a bookcase—the books rendered with that which was then considered to be almost microscopic minuteness of detail; and the photograph, I believe, was one of the earliest emanations from the process simultaneously invented by the Englishman, Fox Talbot, and the Frenchman, Niepce de St. Victor. If that copy of the sun-picture be extant, it must be worth, I should say, a great deal of money."

But surely Fox Talbot and Niepce de St. Victor never simultaneously invented any process. We are afraid that G. A. S. has unfortunately made a slip.

—♦♦♦—

THE Stockport Photographic Society will hold an exhibition next month, which will be confined to members' work only. The exhibits will be shown in the private picture gallery of one of the members of the Society.

—♦♦♦—

WE again warn our readers that our 1892 Annual Lantern Slide Competition closes on September 30th, and that we can allow no extension of time, as the slides will be judged on Monday, October 3rd, by Messrs. F. P. Cembrano, jun., J. B. B. Wellington, and Valentine Blanchard. As previously announced, they will be shown at Pall Mall on the 8th inst., and our prize winners will receive tickets of admission from us.

—♦♦♦—

As amateur photographers we have to bear a good deal,

and many sins are laid to our charge. The two following letters appeared last week in *Truth*:—

SIR,—Within the last month or six weeks a plague of appalling dimensions has settled upon this unhappy town. We are invaded by a mosquito-swarm of photographic cameras, accompanied by their manipulators—male and female. No spot is free from them. Nothing is sacred to them. The beach swarms with them. They lie in wait behind bathing-machines, or in the neighbourhood of public bathing-places, and "take" their prey naked and defenceless. The only distinction observed in this direction is that the male photographer usually frequents the female bathing-place, and *vice versa*. Having taken people on the beach with their clothes off, they swarm up into the Lees and take them with their clothes on. They swoop down upon the children as they gambol at the water's edge, or form picturesque groups at the shrine of Mr. Punch. They obtrude themselves upon couples who by their attitudes and their choice of a situation plainly indicate their desire for privacy. They mount the tops of coaches and omnibuses and take snap-shots at people in the streets or at windows. They post themselves in streets or at windows and take snap-shots at the people on the tops of coaches and omnibuses. So little consideration have they for the worst afflictions of their fellow-creatures that they even seize upon points of vantage in the harbour with a view of making pictures of the miserable passengers as they land from the Channel steamers.

In the interests of our town I write to ask if there is no remedy for this state of things. It is fun, no doubt, to the photographer, but to his helpless subject it is death. People don't like being photographed unawares, and in Heaven knows what attitudes. They won't stand it, and if the nuisance is not put down the public will simply take themselves off to the first place which will guarantee their protection against the camera nuisance. Look, too, at the danger to the Channel traffic. Are there not, I ask, sufficient horrors attached to the passage from Boulogne to Folkestone without superadding to them the awful ordeal of being unconsciously photographed as you step ashore in the last throes of your misery? Unless this sort of outrage is stopped with a high hand, the days of this town are numbered, and I hope that you will, by publishing this letter in *Truth*, awaken my fellow townsmen to a sense of the impending danger.—Your obediently,

ANTI-CAMERA.

P.S.—I see written up everywhere nowadays "Dark Room for Amateur Photographers." They even put it in hotel advertisements. I never read the words without thinking that I should like to alter it to "Black-hole for Amateur Photographers." Don't you think that would be the best treatment for them?

DEAR TRUTH,—Owing to the cholera on the Continent, Papa has been taking us for a tour through the West of England, and I want to tell you how we have been annoyed everywhere by the amateur photographers with their horrid cameras. You can't get away from them anywhere. At all the famous hills, and rocks, and valleys, and waterfalls, just when you are prepared to go into raptures, you find a camera planted, and a pair of photographers—they always seem to go about in pairs—monopolising the best point of view. We tried in vain to escape from them all through Cornwall, and now that we have come here they seem to be thicker than ever.

It is not their photographing scenery, however, that we object to, so much as their photographing their female fellow-creatures. If you are not very careful, you may get taken at any minute, as an "object" in the foreground of a picture. And the people who carry hand-cameras think it the greatest fun to get pictures of girls in undignified attitudes. Now, if there is one thing more than another that any girl with a well-regulated mind is particular about, it is to look nice when she is having her portrait taken, and it's a horrible thing to think that you may be photographed at any minute without knowing it, with your hair and clothes all anyhow, and yourself perhaps all thrown down in a heap, after a long walk, or a game of tennis, in the belief that no one could see you.

You may say, of course, that nobody who knows you sees these pictures. But how are we to be sure of that? We heard the other day of a lady who was sitting at the side of a rock with a gentleman of her acquaintance in a rather indiscreet attitude, when an amateur photographer took the pair of them. He was so pleased with the picture that he handed it round the smoking-room at the hotel, and showed it, among other persons, to the lady's husband. That amateur photographer has started a divorce case. I hope, dear *Truth*, that you will see what a lot of mischief may be done by these prying cameras, and say a word or two which will keep them in order.—Yours affectionately,

MABEL.

—♦♦♦—

The Editor of *Truth* expresses his sympathy, and says he has been deeply touched—an admission at which we are not surprised if he takes these effusions *literatim et*

*verbatim* as gospel truth, or if he expects his readers to do the same. There is a curious coincidence of the two letters coming together, and, forsooth, he publishes a third letter from a firm of professionals, who, amongst other twaddle, say—

"From inquiries that we have made, we believe that the average turnover of the photographers at Eastgate-on-Sea during the present season is some fifty per cent. less than it has been any previous year. We attribute this exclusively to the competition of amateur photographers, of whom we reckon that there are about 892 in the town at the present moment, photographing everybody and everything they can come across. *Their pictures are vile productions, doubtless*, but many of their plates are developed and touched up by short-sighted firms in London; and, as long as there is a photographer at every street corner and in every house ready to photograph gratis all who will give a sitting, people will not pay to have their likenesses taken, even in the superior style which distinguishes the work of our firm.

"We complain of this state of things as unjust, because the amateur photographer, unlike the professional artist, pays no rent for premises, and contributes nothing to taxation, local or imperial. We are paying at the present moment rates to the amount of 5s. in the pound, house duty, and income-tax upon our trade profits. We maintain that if a rival is allowed to come and take the bread out of our mouths, with the result that we shall ultimately cease to contribute the rates and taxes, it is for the public interest, equally with our own, that he should be taxed at least to the extent we are. With this view we would suggest that there should be a tax upon cameras, collected by means of licences, like shooting or gun licences."

The italics are ours. It is an old cry from the poor wretched pro. who turns out second-rate work, that the amateurs are damaging the trade, although "*their pictures are vile productions, doubtless*." Surely if the vileness of amateurs' work is so apparent, why is it that professionals have not carried off every medal at Pall Mall this year. The Editor of *Truth* recommends the formation of an anti-camera association, which shall immediately proceed to pass Acts of Parliament, assisted by *Truth*, M.P., of course, which shall tax cameras, make it penal to photograph here, there, or anywhere. Is it the truth that this is the gooseberry season, and that copy was wanted?

**East London Phot. Soc.**—The Council of the above Society beg to announce that Messrs. E. J. Wall and A. Horsley Hinton have kindly promised to act as adjudicators at the forthcoming exhibition, to be held in the Lecture Hall of the New Tabernacle, Old Street, London, E.C., on Tuesday, the 25th October. Entry forms and full particulars of the "Open Class" competition may be had from the Hon. Secretary, Mr. M. A. Wilkinson, 28, Shacklewell Lane, Kingsland Road, E., on receipt of stamped addressed envelope.

**Mr. Van Choate** suggests a new form of photometry, in which selenium cells are employed to receive the light rays. The instrument, says the *Electrical Engineer*, is in the nature of a balance connected with a differential galvanometer, the standard light being arranged to affect one side of the balance, and the unknown strength the other. Two lanterns are required, in which the lights are placed, and tubes of these are arranged axially in line. The light to be measured is placed in the right-hand lantern, the standard lamp being in the left-hand. Each tube contains a selenium cell, that in the tube from the standard lamp being adjustable by means of a pinion, and having an index finger moving along the index. Now, taking the right-hand coil of a differential galvanometer, one of the terminals is connected to the zinc pole of the battery, the other to the selenium cell and through the resistance coil to the copper pole of the battery. Similarly, one of the terminals of the left-hand coil is connected to the copper battery, and the other terminal with the adjustable selenium cell and to the zinc pole. The galvanometer can be brought to zero by adjusting the resistance coil. The selenium cells being alike, if the lamps are equal, the distance between the selenium cells and the respective lamps will be the same; if, however, the lamp to be tested is inferior to the standard, the cell facing the standard lamp will have to be moved until the galvanometer shows equilibrium. The difference in the distance between the selenium cells and the lamps is indicated on the scale, and gives the basis for the calculation of the relative intensities of the light of the two lamps, calculations being made according to the law of inverse squares.

## Chit-Chat.

THIS is truly "an age of invention." Mr. Blackwood's accession to the ranks of photography must either have been recent, or his historical knowledge of the art superficial. The alteration of the focal length of a lens by the interposition between its anterior and posterior combination of supplementary lenses has been known and put into practice for many years. Mr. J. Traill Taylor has often advocated the plan, and wrote upon the subject in one of the almanacs, if my memory serves me. Ten years ago I became possessed of such a system of lenses; they bore the name of Fergusson, though I was not at the time able to trace the maker. Except upon emergency, the method cannot be recommended; from an optical point of view, it spoils a good lens and makes a bad one worse.

I WAS glad to note that "A. P.," writing recently on amateur emulsion making, in a contemporary, expressed the opinion that most commercial plates would be the better for a more liberal coating of emulsion. Though the demand for a low-priced plate, and the consequent competition, are no doubt the chief factors in bringing into existence the cheap plate of to-day, with its thin smear of emulsion, sadly deficient in silver, such a state of things is greatly to be regretted, for with such materials all-round work of the highest class cannot be done, and I do not hesitate to declare that to this cause alone a large proportion of the indifferent and bad work now so prevalent is due. At the same time the purchaser of cheap plates has no just ground of complaint against the manufacturer, for it is the quantity and not the quality of the emulsion which, in most cases, is at fault. My advice to all beginners is to pay a reasonable sum, and buy a plate which is liberally coated with an emulsion rich in silver, and if the increased outlay is a serious matter let them content themselves with fewer exposures. The gain in the quality of their work will soon manifest itself.

THE evils of halation are still deplored; indeed, the matter was recently discussed in these columns. Plate-backing, unfortunately, is by no means a certain preventive, but the substitution of celluloid films for glass plates reduces the defect to a minimum, and of this Mr. Perkins' cathedral interiors in the "Amateur Photographer's Annual" are good examples.

I AM sorry to see the feud between Mr. Robinson and the Council of the Photographic Society of Great Britain again renewed. No good to either side can come of further discussion, and the public, I am sure, have witnessed enough hard hitting on both sides. Why should columns of vituperation, recrimination, and abuse of the character indulged in by the disputers be foisted on the readers of the photographic papers?

I cannot help contrasting the respective attitudes assumed by the two men most aggrieved, the one cool, calm, and dignified in silence, the other parading his grievances noisily, and with a reiteration approaching monotony before a bored public, which, I am glad to see, refuses to be cajoled into again joining in the discussion.

CHATTERBOX.

**Camera Fittings.**—Messrs. Sharp and Hitchmough, of 101, Dale Street, Liverpool, write to draw our readers' attention to the fact that they have made a speciality of camera fittings for some years; and Messrs. Platt and Witte, of Birkbeck Road, Kingsland, N., inform us that they are making their well-known camera fittings in aluminium as well as brass.

## Letters to the Editor.

### THE ISLE OF MAN.

SIR,—Having just returned from a holiday tour in the Isle of Man, and knowing the number of your readers who visit this splendid hunting ground for the photographer, I venture to think that it will interest my fellow-workers to know that I found an excellent dark-room and a stock of every variety and mark of plates at Harrison's photographic stores, Walpole Avenue, Douglas. The dark-room is on the shop floor, and they will find Mr. Harrison and his son, who is an excellent photographer, very willing to give them every kind of information, and to show their own series of views of all the most interesting and beautiful scenery in the island.

To those wanting a place to spend a pleasant holiday with the camera, I would advise them to visit the island, which abounds in mountain and valley scenery; and for waterfalls in abundance, besides every variety of shipping, fishing, and yachting, the hand-camera man will find plenty to interest him also.

Locomotion by rail or road is very cheap, and accommodation can be had at 5s. to 7s. 6d. per day—bed and board; no extras.—I am, yours, etc.,

BARTON ROAD.

\* \* \* \*

### BROMIDE PAPER.

SIR,—As no doubt at this season of the year many of your readers are making use of bromide paper, both for contact and enlargement, I thought the following hint as to which is the sensitive side might prove useful. I have seen it many times recommended to place the paper upon one's hand, and if it curls upward the top is therefore the sensitised portion, but for amateurs whose hands are frequently hypo stained and sticky I do not think this a good plan. The way I tell is this: Feel across the edge of the paper, and if you can feel the burr left in cutting, that is the right side; since adopting this plan I am never in doubt.—I am, yours, etc.,

FRANK YOUNG.

\* \* \* \*

### THE P. S. G. B. AND REFORM.

SIR,—“Chatterboxes” are too often guilty of indiscretion, saying more than they really mean, and, perhaps, after a little deliberation the writer of your “Chit-Chat” column might have expressed himself differently in his paragraph on the P. S. G. B.

Can honest criticism and temperate condemnation of a system of management and organisation already very widely felt to be imperfect, or at least capable of improvement, be justly styled “mud throwing”?

There are those who consider that the principles which govern the exhibitions not only of our National Photographic Society, but of many other leading photographic bodies, are neither in keeping with the modern development of the art, nor just to its latter-day claims, and have had the courage to speak accordingly. Let us at least give such credit for sincerity of purpose, and hope that it may be productive of good. Your writer is good enough to think my suggestions in a former issue are deserving of attention, and agrees that “reform” is “greatly needed.” Why then attribute any effort in this direction to a petty quibbling or spitefulness which the not very pretty or original phrase, “mud throwing,” would seem to imply?

Let those who think there is or there is not need for reformation lend a hand accordingly, but, considerate of each others views, be wary of entrance to a quarrel as unnecessary as undesirable.

I am ignorant as to “Chatterbox's” identity, but, as I bear him no ill-will, trust he will take no offence at my remarks.—Yours faithfully,

A. HORSLEY HINTON.

\* \* \* \*

### LEYTONSTONE CAMERA CLUB EXHIBITION.

SIR,—In reply to the query of the numerous applicants for entry forms for our forthcoming Exhibition on November 10th, 11th, and 12th next, as to who are the judges? will you kindly announce that Mr. A. Horsley Hinton, Rev. F. C. Lambert, and Mr. E. J. Wall have kindly consented to officiate on that occasion.

Intended exhibitors of apparatus, etc., and those wishing space for stalls, are requested to send in their applications as soon as possible. Thanking you in anticipation, and apologising for taking up so much space in your valuable journal, I am, yours, etc.,

ALBERT E. BAILEY

Rose Bank, South West Road,  
Leytonstone.

(Hon. Sec., Ex. Com.)

### MEDALS AT PALL MALL.

SIR,—Can you inform an inquisitive enquirer why the medals at the Pall Mall Exhibition are awarded each year to a favoured clique, irrespective of whether their work is best or not? While there are several who are unquestionably fully entitled to the honour that they receive, yet it is difficult to understand why 212, “Frost and Sunshine,” should have been selected for a medal, and why a similar set by the same exhibitor should also have been so honoured last year. Several other medal awards are open to the same objection, viz., that there are many far better pictures in the room that receive no recognition whatever.

A second puzzle is why a few men can have eight or ten frames each, hung together, and as nearly as possible in the same position in the room year after year, as though certain spaces were considered the private property of certain individuals, while the work of an outsider is divided up, sets even being broken and fitted in anywhere. Assuming that it is impossible to group all the work of each exhibitor together, it is manifestly unfair to so favour the same special few each year at the expense of the majority. On looking through the catalogue I can only find seven names of those who send more than three frames and have them all arranged in consecutive numbers; of these seven, four are members of Council of the Society, and another is a well-known exhibitor and medalist.

It is impossible that photographers generally can feel confidence in the good faith of the management of the Photographic Society of Great Britain when the same state of affairs is revealed at every exhibition, especially considered in connection with the very disagreeable incidents last year. One cannot but feel consideration and sympathy for Mr. H. P. Robinson in the treatment he then received from the Society that he had worked for for so many years, and be tempted to ask how far that treatment was due to the jealousy and personal feeling of a certain clique.

A solution of these problems would be very acceptable to your correspondent,  
SPECTATOR.

\* \* \* \*

### FILM SLIDES.

SIR,—I am pleased to see your new contributor “Chatterbox,” but in his very first paragraph, in which he speaks of light slides for plates and films, he is somewhat unfortunate. As his suggestions have already long been anticipated, it is now getting on for four years since I placed my film slides, which are “capable of holding two films, and should be about half the weight and thickness of an ordinary dark-slide, and the shutter should draw completely out, and finally the film should be held down on all four sides.” I enclose you circular, from which you will see that these conditions are fulfilled. These slides were advertised some three years since in both the AMATEUR PHOTOGRAPHER and *British Journal*. I have supplied many dozens to London trade houses, and they have been extensively sold otherwise. In regard to American film slides, the American firm making them very quietly annexed them about two years since (of course with acknowledgement), and are now sending them out as theirs. I have seen several American visitors here with them. I trust it will be some satisfaction to “Chatterbox” to know that these slides are already in the market, and that he will duly acknowledge this in his next communication.—I am, yours, etc.,

J. M. TURNBULL.

\* \* \* \*

### A NEW USE FOR “SOLIO” PAPER.

SIR,—Some of your readers may not be aware that by toning Eastman Solio paper in the bicarbonate bath advocated by Mr. Welford, fixing and washing as usual, carefully avoiding the alum bath, and finally immersing for a few minutes in slightly warmed water, the film easily separates from the paper and can be transferred to opal, paper, or any other support desired. Slight enlargement takes place during transference—a half-plate print in my possession, transferred to rough drawing paper, measuring 7½ by 5½. I believe that you, Sir, in an article on Cresco Fylma published in the AMATEUR PHOTOGRAPHER last autumn, advocated tentatively the transference of gelatino-chloride film to other support by means of that enlarging solution, expressing at the same time a doubt as to whether the film would prove strong enough. I have found the film of the Solio paper all that could be desired in this respect, in fact its toughness was wonderful. If handled with anything like reasonable care, the film is absolutely free from distortion. It should be dried thoroughly, lying perfectly flat, then immersed in the alum bath, washed, and finally dried.—Yours, etc.,

E. E. SKINNER.

Painswick, Glos., September 26th, 1892.

## STRIPPING GELATINO-CHLORIDE PRINTS.

SIR,—As Mr. Forret, judging from his initial remark, is one of those most exceptional individuals—a *rara avis*, in truth—a photographer without even a few spoiled negatives, it is natural for him to prefer a method whereby the support on which the print is dried can be used for ever; but the average amateur, for whose benefit the paper was written, can, I think I may safely assert, supply one spoiled negative for, say, every two dozen prints he wishes to enamel; for, though I recommend this method of finishing for a certain class of photographs, amongst which I would place instantaneous ones, I would by no means advise amateurs to make a habit of finishing their prints in this way; for some photographs, indeed, and especially for portraits, it is most objectionable.

Would that all professionals were of this way of thinking, and that the more artistic matt-surface was oftener adopted for portraiture! But I suppose they have their answer ready, 'twould be "caviare to the general."

To return to Mr. Forret and his criticisms. One piece of glass is, with ordinary care, quite sufficient to enamel at least two dozen prints; I have used the same plate for months, and have never once been troubled with scratches showing on the finished prints, and this is easily accounted for. In the first place, one must not press with all his force when using the knife, or he may, if his knife be extra well tempered, mark the glass, though it is more probable that he will break it; but the knife should be run backwards and forwards along the straight edge till a clean cut is made; and, in the second place, the prints are not, or ought not to be, trimmed till after enamelling, so that, if by any chance scratches should be made on the glass, they fall on the edges that are to be subsequently removed.

Vulcanite is, of course, a different matter, and Mr. Forrest will see, if he refers to my paper, that I mention neither it nor iron as a support for gelatino-chloride prints during enamelling.

My reason for cutting round the print is this: the edges of the backing-paper, being firmly attached to the glass, would, if not separated from the photograph, be almost certain to tear it on an attempt being made to strip it from its support; and the advantage of having the waterproof paper slightly larger than the print is that by this means there is no fear of the photograph curling when dry, and becoming detached from the backing-paper at the edges.—Yours truly, W. PITCAIRN CRAIG.

September 26th, 1892.

\*\*\*

## ANOTHER NEW BATH.

SIR,—May I offer the readers of the widely-circulated AMATEUR PHOTOGRAPHER a new toning bath for gelatino-chloride papers? I have only used it for the Ilford brand, but I daresay it will be found useful for any other make:—

Sodium chloride .. .. .	64 gr.
Ammonia sulphocyanide .. .. .	15 "
Gold chloride .. .. .	2 "
Water .. .. .	10 oz.

Print slightly deeper than required in finished print. Immerse in toning bath without previous washing. When toned, pass direct to fixing bath (hypo 2 oz., water 20 oz.), and then wash as usual. That is all, and I hope those who try the bath will report their experience.—Yours sincerely,

EDWARD MASON.

\*\*\*

## AMIDOL.

SIR,—Several correspondents who know that I take an interest in matters photographic have written me *inter alia* as to my opinion of the new developer. Messrs. Fuerst Bros. having very kindly sent me a sample of Amidol, I hasten to lay the results of my experience before your readers. For medium speed plates and for bromide papers I consider amidol in many respects superior to pyro, and in all points preferable to hydrokinone, iron, or Rodinal. The use of bromide and the amount of dilution will depend upon the plate and the exposure, but for extra rapid and thinly coated plates amidol is far behind pyro and soda in density and detail-giving properties. It may, however, be advantageously used in conjunction with pyro-soda in the proportion of about one of amidol to five of pyro. This will bring up the image more rapidly, and apparently induces an amount of delicate detail to which density is given by the pyro-soda. As a developer amidol is savage in its action and not greatly under the influence of bromide; in my hands I find yellow prussiate of potash makes a more efficient restrainer, or a

few drops of 10 per cent. of citric acid solution, which simply acts by diminishing alkalinity. With the combined developer an ordinary plate may be finished in two minutes. One of the stumbling-blocks to improvement of general work among professional photographers is the need of busy men for rapid development, and a curious ignorance of the properties of the chemicals with which they deal. One of your contemporaries holding last week an amateur up to good-humoured ridicule, described him as burning holes in the hearthrug with pyrogallic acid! When such woeful ignorance of the nature of the most used and presumably best known of all photographic chemicals is disclosed in a journal devoted to the interest of the trade, it is not to be wondered at that the professional often remains in darkness regarding elementary principles.

## FORMULÆ.

## Sulphurous Acid Pyro Stock Solution.

Metalbisulphite of potash (not soda) .. ..	1 oz
Pyrogallic acid .. .. .	1 "
Water .. .. .	8 "

Dissolve the pyro in the water, and add the potash salt. Shake till sulphurous acid gas can be smelt.

## Amidol Stock Solution.

Amidol .. .. .	2 scruples.
Sulphite of soda .. .. .	7 dram.
Water .. .. .	5 oz.

## Accelerator.

Pure carbonate of soda (crystals) .. ..	2½ oz.
Water .. .. .	18 "

Use for normally exposed plates, pyro stock solution ½ oz.; amidol stock solution, 1 dram.; soda accelerator, 4 oz.; water, 4 oz., bromide of potash 10 per cent. solution, according to plate, say, ½ dram. My own plan is to have three dishes, a highly restrained, and a strong developer on either side of a normal developer. It is time the one-solution fiend were relegated to the studio of one-batch plates and equal exposures.

I am, etc.,

H. S. SCHULTESS-YOUNG, M.A.

\*\*\*

## EXPOSURE METERS.

SIR,—I have followed the letters and remarks which have recently appeared in your valuable paper with much interest, but from practical experience I must certainly take exception to the remarks of "Chatterbox" in your last issue.

Now, sir, I was just as firm a believer in "judgment and brain" as "Chatterbox," and used to look upon such helps as tables and meters with scorn.

On my recent holiday, however, I was induced by a friend to give one of these instruments "of scientific jugglery" a trial which proved far more severe for the instrument than even I anticipated. I only took two dozen whole-plates away with me, as, on consulting the "Amateur Photographer's Annual," I found that at the various towns I was to visit there were photographic dealers, so I took the trouble to write to them asking if they stocked the plates I use, and on receiving a satisfactory reply felt happy. When, however, I arrived, I could only get the plates I required at one dealer's out of five, consequently I had six different brands of plates, and the only guide to the speed being the list you recently published.

These plates were exposed on all kinds of subjects, from the interior of a cathedral, which took 1½ hours' exposure to some yachts racing. I used the meter in conjunction with the list you published, and out of seven dozen plates I had only two failures, and these were caused by drawing the slide before closing the shutter after focussing.

The negatives are as near perfect as I think it is possible to get them, taking into consideration the various subjects and conditions under which they were taken.

I have always been fairly successful in my exposures, but generally calculate on a certain percentage of failures. I can only attribute my unexpected success to the meter and the table of speeds, "which I find more reliable than the maker's statements." I think if "Chatterbox" were to give the meter an "intelligent" trial, he will find it give the correct exposure in nine-nine cases out of 100.

I am afraid I shall be at once classed as an individual who has not the judgment and brains which are considered so necessary to make a successful photographer. I myself am another "disinterested" correspondent, and know neither the

patentee nor maker of the instrument, or have ever had a communication from them.

I cannot think, after reading the remarks in your paper, but that "Chatterbox" is biased against these helps to correct exposures, which they are undoubtedly are.

I only speak from my practical experience, and the results I have obtained warrant my making this reply.

Apologising for the length of this, I enclose my card, and remain, yours, etc.,

METER.

EYES OPEN.

SIR,—A man of slouchy and shabby appearance, dark hair (but light fingers) appears, to be going his rounds amongst your advertisers. He carries the paper, and asks to see whatever you may have advertised, and while looking at goods, asks if you can throw in anything else. Possibly you turn round to see what else you can oblige him with, when something goes into the pockets of his very roomy frock coat. In this way I have just lost a new drill-chuck, value 10s. 6d., from off my lathe. I have made inquiries and find he is an old stager. His age I should think to be about forty-five. If anybody should have the pleasure of making his acquaintance, please hold him till I come, as I have a lodging prepared for him.—Yours, etc.,

H. S. LARGE.

## General and Photographic Chemistry. — IX.

By E. C. CONRAD, F.C.S.

### THE NON-METALLIC ELEMENTS AND THEIR COMPOUNDS.—(Continued).

#### BROMINE (Br=80).

Oc.: Bromine is not found free in nature, but in combination with calcium and magnesium it occurs in seawater and in the water of many mineral springs, also in seaweed (kelp), sponges, and in many marine animals. A native bromide of silver is also known. M.: Chlorine expels bromine from its combinations with the metals, and the element can be obtained in the free state by taking advantage of this property of chlorine; but bromine is usually prepared by heating one of its salts with manganese dioxide and sulphuric acid. Eq.:  $2\text{KBr} + \text{MnO}_2 + 2\text{H}_2\text{SO}_4 = \text{K}_2\text{SO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O} + \text{Br}_2$ . It will be seen that this is a similar reaction to that given for the preparation of chlorine. P.: The name bromine is derived from a Greek word signifying a stench, and it is a dark-red poisonous liquid of an exceedingly irritating odour (bromine and mercury are the only elements that are liquids at the ordinary temperature). Bromine is nearly three times as heavy as water, in which it is slightly soluble, one part of bromine dissolving in thirty parts of water. The solution possesses the colour and smell of bromine, and on cooling, a hydrate of the composition  $\text{Br}_2 \cdot 10\text{H}_2\text{O}$  separates out. Bromine boils at  $60^\circ$ , and freezes at  $-23^\circ$  to a reddish-black mass. Bromine has a strong affinity for hydrogen, and its solution bleaches by oxidation in the same way, but to a feebler extent than a solution of chlorine. U.: Bromine water is used as an oxidising agent. U. P.: Bromine water has been proposed as a reducer and hypo eliminator; several of its salts are of great importance, and will be given under the headings of the various metals. Tests.—Bromine can be recognised by its colour and smell, and also by causing the reddish-brown vapour to act upon starch paste, when a yellowish bromide of starch is formed.

HYDROBROMIC ACID,  $\text{HBr} = 81$ .—Oc.: The same as given under the heading of Bromine. All native bromides are, chemically speaking, salts of this acid. M.: Bromine combines with hydrogen, but much less energetically than

chlorine. A mixture composed of equal parts of the gas can be exposed to direct sunlight without explosion, but combine on passing through a red-hot tube, or by the action of a series of electric sparks. (2) By passing sulphuretted hydrogen gas through bromine water, sulphur, sulphuric, and hydrobromic acids are produced. Eq.:  $2\text{H}_2\text{S} + 4\text{H}_2\text{O} + 10\text{Br} = \text{S} + \text{H}_2\text{SO}_4 + 10\text{HBr}$ . The sulphur must be filtered off and the hydrobromic acid distilled from the sulphuric acid. (3) By suspending amorphous phosphorus in water and adding bromine. Eq.:  $\text{P} + 4\text{H}_2\text{O} + 5\text{Br} = \text{H}_3\text{PO}_4 + 5\text{HBr}$ . P.: Hydrobromic acid is a colourless gas which fumes in the air, and if inhaled produces violent coughing. Under the action of cold it is condensed to a liquid and at a temperature of  $-73^\circ$  to a solid. Metallic potassium, chlorine gas, and metallic peroxides decompose it; chlorine also decomposes its solution. Hydrobromic acid gas is readily absorbed by water; a solution of 48 per cent. of the acid has a S.G. of 1.49 fumes in the air, and boils at  $126^\circ \text{C}$ . This acid combines with metals, forming a series of salts called bromides, which are all soluble in water, with the exception of the bromides of silver ( $\text{AgBr}$ ), mercury ( $\text{Hg}_2\text{Br}_2$ ), and lead ( $\text{PbBr}_2$ ), which are insoluble. Platinum and gold bromides are decomposed on ignition into the metal and free bromine, which volatilises. Most of the other bromide, are converted into an oxide of the metal and free bromines on heating in air. Potassium and sodium bromides are not decomposed by heat. U.: To make bromides. U. P.: The acid is not employed directly, but potassium bromide is used in emulsion-making, and also as a restrainer in development. Tests.—(1) By decomposing a bromide with sulphuric acid and manganese dioxide, bromide is given off, and can be recognised by its colour, smell, and action on starch. (2) The free acid or a soluble bromide can be recognised by adding a little dilute nitric acid and a solution of silver nitrate; a yellowish-white precipitate of silver bromide is produced, which is only slightly soluble in strong ammonia solution, but can be filtered off and decomposed by strong hydrochloric acid, when free bromine is liberated.

OXIDES OF BROMINE.—Several of these oxides are presumed to exist, although at present they have not been isolated. The oxyacids of bromine are as follows:—

*Hypobromous Acid*,  $\text{HBrO}$ .—M.: By adding mercuric oxide to bromine water. Eq.:  $\text{HgO} + \text{Br}_2 + \text{H}_2\text{O} = \text{HgBr}_2 + 2\text{HBrO}$ . It is also formed by adding excess of bromine to silver nitrate solution. P.: It is a straw-coloured liquid, bleaches strongly, and decomposes about  $60^\circ \text{C}$ .

*Bromic Acid*,  $\text{HBrO}_3$ .—M.: By passing chlorine through bromine water. Eq.:  $\text{Cl}_2 + \text{Br}_2 + 6\text{H}_2\text{O} = 10\text{HCl} + 2\text{HBrO}_3$ . P.: This is the most important oxyacid of bromine. It has a strong acid reaction, bleaches, and is decomposed at  $100^\circ \text{C}$ . Its salts are called bromates, and are all soluble, but the argentic and mercurous bromates dissolve with some difficulty.

*Perbromic Acid*,  $\text{HBrO}_4$ .—M.: By the action of bromine on perchloric acid. P.: It is a colourless oily liquid more stable than the other acids of this series. All its salts are soluble in water.

The s.s. "City of Richmond," which has made such successful trips this summer to the Norwegian Fjords, is now to make a series of winter cruises to that most picturesque place which has well been named the Garden of Europe, namely, Madeira. Of all photographic paradises this is the finest, and the only regret one has is that photography is unable to reproduce the amazing colours as well as the forms of the innumerable blooms and vegetation which everywhere meet one's eye. The itinerary includes Lisbon, Madeira, Teneriffe, and Grand Canary. Of the comfort and ease on board the steamship, our special correspondent who described so graphically his "Trip to Norway," speaks most highly, and under new management there is not the slightest doubt that the slight hitch which occurred at the starting of the Norwegian trips will not occur again.

# How to Make a Set of Photo-graphic Apparatus.

By H. J.

## CHAPTER VIII.

### ENLARGING APPARATUS.

UNTIL very recently the use of enlarging apparatus was confined to only a certain class of well-to-do amateurs: the expensive lantern required for artificial-light enlarging, and the necessity of a special room for daylight use, made

mentioned hereafter, they allude to apparatus of the above size.

To make an enlargement the parts C and D must be moved along the baseboard to their proper distances, and the negative inserted in the rising front F. The focussing screen then being placed in the dark slide, and a lamp behind negative, correct focus can be easily obtained. The sensitive paper can then be placed in slide, and a strip of magnesium ribbon fixed in each hole in H and the shutter of dark slide being

FIG. 65.

FIG. 63.

this fascinating branch of photography quite impossible for us who are not blessed with a large share of this world's goods; and as it is for this class that these papers are intended, I have designed the camera which I am about to describe, for the use of magnesium ribbon, this material being now very cheap, and enlargements can also be made by it without condensers, thus enabling us to enlarge from any size negative without adding to the cost, which, if enlarging from anything above quarter-plate by the old-fashioned way, is considerable.

Before commencing with the actual making, I will describe the various parts of camera and the method of working them, as this will render good service when I am describing the details of manufacture later on.

Fig. 63 shows elevation of camera, A being the body, B the baseboard, C the middle part which carries the lens, D the main part of front to which bellows are fixed, E the cross sliding front, F the rising and falling front in which negative is placed, G frame to carry ground-glass, which is used to diffuse the light, H brass strip pierced with holes, to which magnesium ribbon is suspended, I dark slide.

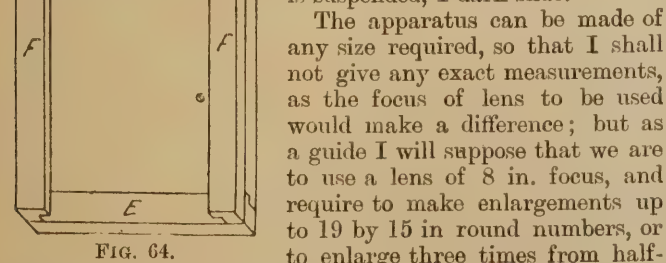

FIG. 64.

plate negatives. For this we shall require the body of camera to measure 21 by 16 in., and to open out about 4 ft., therefore it must be understood that where sizes are

drawn out, the ribbon can be lighted strip after strip, and on developing the paper it will be found that each part has been evenly exposed. Of course it will be necessary to use more light with some negatives than others, as it would be with any apparatus, but this can only be found out by experience. By using the rising and cross fronts, any part of a negative can be enlarged from by moving the sliding parts so as to bring that portion opposite the lens.

Having given this short explanation by way of introduction, we will now proceed with the making of camera, which will be easy compared with the subject of the last two chapters. The material should be well seasoned, but any kind of wood will do, even pine if extreme cheapness is required.

The first part will be the baseboard. For this prepare two

FIG. 66.

pieces 4 ft. long, 3 in. by  $1\frac{1}{4}$  in.; along one edge of each piece run a groove, as shown at K, figs. 68 and 69, which show sections of these pieces when finished; then from one end for a distance of six inches cut away half an inch in width (see L, fig. 66); these pieces must be fastened together by a piece  $1\frac{1}{2}$  in. wide screwed on top of them at the cut end (M, figs. 66 and 67), and at the other end by a piece about  $\frac{3}{4}$  in. thick screwed on the ends (see N, fig. 63). This completes the outside frame of baseboard. We now want two pieces  $1\frac{1}{2}$  in. wide, and 2 ft. long; these are to carry the middle piece C, and must have a tongue on one edge to fit the grooves of outside frame, and a similar groove on the other edge (see section O, fig. 68). These two pieces can be placed in the grooves in outside frame and a piece of wood or brass screwed on the ends as at P, fig. 66, keeping it level with them at both top and bottom. The other ends will be fixed by screwing them to C, but as that is not yet made, a strip should be screwed on top temporarily, to hold them in their place. Another piece can now be prepared, the right width

to slide between the last two pieces, with a tongue on each edge fitting the grooves in the former, and the same length—that is, 2 ft. This is shown in section at R, fig. 69. To insert this last piece in its place it will be necessary to take off the piece P, which can be fixed firmly afterwards, as it will not have to come off again. The baseboard is now

FIG. 67.

finished for the present, and the body can be made. This simply consists of two sides and a top. It can be put together in the same way as I described in the chapter on making cameras, and must be the same width inside as the baseboard is wide at the cut end, the uprights being 22 in. long; all three pieces must be 6 in. wide. When put together, screw the bottom ends of uprights into the baseboard at L L, fig. 66, keeping them exactly upright and square each way.

This being finished, the middle piece C can be made. It is a piece of 1 in. board, made so as to just fit easily in camera body; and in the centre each way an opening must be cut about three inches square for the lens; a round hole will do as well if you are the possessor of a bit to bore large enough, but if not, the square hole will be easier to make.

The front D must be made the same size, and in the same way; only the hole will be the size of a half-plate. These two parts can now be screwed on to their respective foundations in baseboard, C being screwed to O, and D to R. One screw is shown at S, fig. 67, as fixing D, C being fixed in the same way.

I find that I have omitted one little detail, and I will rectify it at once or it may cause a difficulty later on. It is this: in screwing on the cross piece M, instead of keeping it level with the ends of side pieces, it must be allowed to hang over them about  $\frac{3}{8}$  of an inch, for a reason which will be shown hereafter.

The cross front can now be made and fixed to the front D. It does not require much explanation, being simply a rabbetted strip screwed across top and bottom of the front, and a piece fitted between them and held in its place by tongues which fit the aforesaid grooves. In making this sliding piece the grain of the wood should run from top to bottom, not from side to side, or, in other words, the tongues should be formed on the end grain of the wood; the strips will then keep it from warping and twisting, which it would be certain to do if made the other way of the grain.

The rising and falling front is made in the same way, the above remarks applying to it as well, and the guide strips must be screwed to the sliding cross front as shown

FIG. 69.

by screws, so that the cross front will always carry the rising front with it. Each sliding front will require a hole cut out of it the size of a half-plate, the holes in the two sliding pieces and the main front being cut so as to intersect when the fronts are all level. The rising front must have a small strip of brass screwed across each corner on the outside, and a small turn-button top and bottom inside, all of them being let in flush with the surface of the wood, so that they will not interfere with the front sliding up and down. They are, as I have no doubt most of my readers have seen, to hold the negative in position, and are better than making a rabbet for it, as the whole

negative is available except the extreme corners, while a rabbet cuts off an eighth of an inch all round, which is sometimes wanted in the picture.

A slot must be cut in rising front, and a plug nut inserted in the cross front, so that a milled head screw can be used to hold the front in position; the cross front will keep in its place itself, wherever it is required. Both of the fronts can be made of half-inch board. The frame G must be made and fixed to rising front; it consists of two sides and two ends joined together so as to form a bottomless box 7 by 5 in. inside, and about  $1\frac{1}{2}$  in. deep. Before putting it together, a small groove should be run about  $\frac{1}{4}$  in. from the edge, and a piece of ground-glass inserted in this groove before nailing the last side on it can then be fixed to the

FIG. 70.

rising front by screwing through the latter from the inside into the edges of the former, keeping the ground-glass farthest away from the front. It will, I should think, be almost unnecessary to say that the frame, or rather box, should be kept at an equal distance all round from the hole in which the negative fits. A strip of brass must now be obtained about 11 in. long, and small holes drilled at intervals of half an inch along the whole length, with the exception of  $2\frac{1}{2}$  in. at each end. It must then be bent at right angles through the outside holes, and a small hole drilled through the ends to screw it to the box by; it is shown in its place in fig. 65, which is a perspective sketch of the rising front when removed from its grooves.

It will be noticed that when the front D is drawn out to its full extent, and the middle part C is stopped half-way or thereabouts, there is nothing to prevent D from lifting up and shaking sideways. To remedy this, a piece of  $\frac{3}{4}$  in. board must be fitted between the grooves of side pieces, and screwed to the front end of the sliding piece R, which carries the front D. This guide piece (as we may call it) is shown at T, figs. 70 and 71.

As the camera would be an unwieldy article if it could not be folded when not in use, it is necessary to make it to fold up. This I accomplish by hinging the baseboard close up to camera body so as to fold up, then again where the top of body comes, so as to fold down, and yet again so as to fold up. The hinges must first be screwed on in their places, or rather let into their places, as they must be level with the wood and inserted with the round part downwards so as not to interfere with the sliding portions, as they will have to pass over them. After all have been fixed they must be taken out again and the baseboard cut asunder with a fine saw; the hinges can then be screwed on again without any trouble, with the certainty that they will not require any alteration. The baseboard being jointed will not cause the apparatus to be weak when in use, as the sliding parts will stiffen the joints when they

FIG. 71.

are drawn out, and moreover it will be supported on a table so that it will practically be as firm as though not cut at all. I will now draw this chapter to a close, and in the next the camera will be completed, but as the fittings will be necessary in order to complete it as far as we have got, I give a list below of what is required, with the prices attached, according to my usual plan:—

	s.	d.
3 pair hinges for baseboard .. ..	1	0
1 milled-head screw for rising front ..	0	5
2 brass strips, D, fig. 66, and H, fig. 65 ..	1	0

This is all the fittings yet described; the remainder will be given in the next chapter, in which I shall also show how to make the bellows, as these are the most expensive items. I mention this here so that no one may be deterred from commencing work, as the bellows can be made the exact size to fit in body, whatever size it may be made.

**Discovery among the Minor Planets.**—An announcement comes from the Central Bureau at Kiel for the Propagation of Astronomical Telegrams to the effect that Dr. Wolf, of Heidelberg, picked up a new minor planet on September 13 at 9 h. 57 m. 3 s. (Heidelberg time) in right ascension 23 h. 46 m. 8 s. and North Polar distance  $95^{\circ} 50'$ ; with a daily motion of  $-48$  s. in R.A. and  $+8'$  in N.P.D. It was of the eleventh magnitude. Another planet found by Dr. Wolf on September 17 at 12 h. (Berlin time) (11 h. 6 m. Greenwich time) turned out, on comparison, to be identical with Frigone. It was in R.A. 23 h. 31 m. 8 s. and N.P.D.  $95^{\circ} 8'$ , with a daily motion of  $-52$  s. in R.A. and  $+8'$  in N.P.D., and was of the twelfth magnitude. The telegram does not state whether these discoveries were made by means of photography, but such is probably the case, as Dr. Wolf has employed this method on former occasions. The planet would betray itself in a photograph by trailing a line on the plate, owing to the fact that it moves relatively to the stars, whose images will be merely dots, the telescope being driven by clockwork so as to follow the stars in their apparent daily motion round the earth. Where photography is not employed the observer laboriously compares all the stars seen in the telescope field with charts specially prepared, showing the stars in the region down to an extreme degree of faintness. If one of these is found to have shifted its place appreciably it must be a planet or comet, since the stars are at such immense distances from us that any motion on their part is dwarfed practically to nothingness.

## Lantern Condensers.\*

By W. I. CHADWICK.

WHEN a beam of parallel light A A (fig. 1) falls upon a convex lens the rays will be bent towards the centre and made to converge approximately to one point  $f$ , which is called the principal focus. If, on the other hand, a diverging beam of light proceeded from a point at  $f$  the rays could be traced back—that is to say, they would, after leaving the lens on the other side, proceed parallel to A A.

FIG. 1.

If the point of light be brought nearer to the lens than the principal focus  $f$ , as shown at A (fig. 2), the lens would have too much work to perform to send the rays parallel, and they would proceed from the lens still divergent as B B, though not as much divergent as before they entered the lens.

When the point of light is outside the focus, as at A (fig. 3) the rays on the other side of the lens will meet at some point B (approximately), and if the point of light be moved to B the rays would meet at A; so we see that A and B are reciprocal, and are called the conjugate foci, one having a distinct relation to the other. As the point of light A (fig. 3) advances towards  $f$ , the conjugate B will move away from the lens on the other side, but not in the same proportions as A advances, for the longer focus always moves more rapidly than the shorter. If we assume the lens to be 3 inch focus, the conjugates A and B being equal, will be 12 in. apart or 6 in. from the lens on each side.

FIG. 2.

In fig. 4 we have caused the point of light A to be brought nearer to the lens than is shown in fig. 3, let us say to 4 in. The conjugate B has moved further away from the lens—to 12 in. (4 in. and 12 in. being the conjugates of a 3 in. focus lens), and if we move the point of light A still nearer to  $f$ , say to  $3\frac{1}{2}$  in., the conjugate B will be found at 21 in. on the other side, and so on as A approaches the lens, B recedes, until at length when the point of light arrived at  $f$  parallel rays would be produced as shown in fig. 1.

FIG. 3.

Now, let us see how these few remarks apply to a lantern condenser. One important function in a condenser is to collect as much light as possible, and in passing it on through the slide, the rays now forming the picture must converge to a point somewhere in front, and that somewhere is in or about the centre of the objective in use—that is to say, the objective must be at B fig. 3, or at B, fig. 4.

When a lantern and screen have been assigned to their respective places, there is only one position for the objective in use to make the picture focus on the screen, and as the conjugate B must meet in the objective, and, as has been shown, this conjugate has another conjugate A, which is the point of light, it is quite clear that the focus of the objective defines the position of the light.

If, then, the condenser be 3 in. focus and the objective 12 in. (or such as would require the conjugate B at 12 inches), then the point of light must be at 4 in. from the lens, as shown in fig. 4, but if an objective of 6 in. focus be applied the light must be moved back to 6 in., as shown in fig. 3.

Now the law that "diverging light varies in intensity inversely as the square of the distance," shows clearly that by moving the

\* Read at the Stereoscopic Club.

light back from 4 in. to 6 in. we have lost about one half of it, and demonstrates the fact that whatever be the focus of a condenser best suited to a long focus objective, it cannot possibly be near so good—as a light collector—as a shorter focus condenser would be when shorter focus objectives are employed.

There is a limit to the shortness of focus for a lantern condenser on account of the heat given off by the incandescent lime, and when this limit has been reached for use with a short focus objective, the condenser must inevitably break if an objective of longer focus be employed.

Single lenses, such as are shown for simplicity in explanation at figs. 1 to 4, are never used as lantern condensers, for two good reasons, firstly, they would be too thick to stand the heat given off with the light; and, secondly, they suffer from a defect known as spherical aberration, of which we shall have something to say presently.

A biconvex lens of 3 in. focus and  $4\frac{1}{2}$  in. diameter would be about 2 in. thick, and would not stand the heat for many minutes.

Now let us see what two lenses will do.

FIG. 5.

In fig. 5 we have two plano-convex lenses, under similar conditions as explained in reference to fig. 1; divergent light from a point A immerses practically parallel, and parallel light falling upon the second lens is conveyed to B; here we have very nearly the same conditions as at fig. 3; but these two lenses, which are each 6 in. focus, are only half the thickness, consequently they are less liable to fracture by heat. If we place the point of light near to  $f$ , the rays immersing would diverge (see fig. 2), and these diverging rays, falling upon the second lens, would converge to the conjugate  $B'$ ; but these lenses, being of equal diameters, the second lens would not take up all the diverging rays from the first lens, the marginal rays would be thrown into the mount, and therefore lost, as shown in fig. 6.

FIG. 6.

Where for a pair of 6 in. focus plano-convex lenses,  $A B'$  represent the conjugates of the second lens at 12 in. each;  $C O'$  the conjugates of the pair of lenses, viz., 6 in. on each side;  $B B'$  the 12 in. and 4 in. conjugates of the pair of lenses, and demonstrates the fact that of a 4 in. diameter front lens only  $3\frac{1}{2}$  in. of its diameter is utilised when the 12 in. objective is employed.

If we introduce a third lens, which should be of long foci and consequently very thin, we should be able to get the light within the distance of say 2 in.; this would diverge the rays, and the middle lens would receive the diverging rays and pass them on practically parallel to the last lens, which would converge to the conjugate B, as shown at fig. 7.

FIG. 7.

The advantage then is that we get a thin lens of suitable focus and diameter close up to the light, and with such a combination as shown at fig. 7 light may be collected and utilised up to an angle of 95 deg., which is not possible with any single or double condenser.

Very early in this communication it was said that rays converged *approximately* to one point; for, as a matter of fact, no single lens having spherical surfaces has the power to converge rays *absolutely* to one point, so that it is not possible by any single lens to obtain an exact focus.

Sir John Herschel has shown that the spherical aberration may be reduced to one-fourth of that of a single lens in its very best form, by means of two plano-convex lenses having their convex surfaces towards each other, and their radii as 1 to 2.3.

But it was Dollond who, over one hundred years ago, first laid down the principle that spherical aberration of single lenses is proportional to the cube of half the angle of the transmitted rays. But, says Dollond, "if two glasses be so proportioned and situated that the refraction be equally divided, then they will each produce a refraction equal to half the required angle, and therefore the refraction being in proportion to the cube of half the angle taken twice, will be but a fourth part of that which is in the proportion to the cube of the whole angle, because the cube of one is but the eighth part of the cube of two, and so the aberration where the two glasses are rightly proportioned is but the fourth of what must inevitably be when the whole is performed by only one lens."

Now, by the same reasoning, where the refraction is divided between three lenses, the aberration will be found to be but a ninth of what would be produced by a single lens, because three times the cube of one is but one-ninth of the cube of three.

To those who have followed what has now been said the advantages of a triple condenser for lantern purposes must be manifest.

The condenser which we now introduce to your notice is a triple combination constructed on the lines here advanced, though the foci of the lenses mentioned to illustrate our remarks are not necessarily those we have adopted.

No reference has been made to the density or quality of glass, or to the various forms of condensers, and some other matters, with a desire not to make this communication too technical.

## Exhibitions.

SOCIETY.	ENTRIES CLOSE.	OPENS.	CLO.	ADDRESS OF SECRETARY.
P.S.G.B. ... ..	—	Sept. 26	Nov. 10	The Assist. Sec., 5a, Pall Mall East

## PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The Exhibition of the Photographic Society of Great Britain was opened at 5A, Pall Mall East on Saturday last the 24th inst, with a conversazione which was unusually well attended. The guests were received by Captain Abney and the members of the Council.

The judges for this year, as we have already announced, were F. P. Cembrano, jun., W. England, W. E. Debenham, F. Hollyer, J. Traill Taylor, with Captain Abney and Andrew Pringle as scientific experts; and they awarded medals to the following exhibits:—

No. 5. Marsh Idyl. Quiet Life Homeward In the Welsh Mountains Change of Pastures Sunset on the Lower Thames	By Karl Greger.
--	-----------------

- |  |                             |
|--|-----------------------------|
| 48. The Estuary of the Blyth   | } By B. Gay Wil-<br>kinson. |
| 49. A Sunset Calm  |                             |
| 50. Westminster.   |                             |
| 51. The Peaceful Evening Hour  |                             |
| 52. Where Tempests Beat and Billows Roar   |                             |

| 146. A Portrait. By F. Muller.   |                             |
| 184. Worn Out. By J. E. Austin.  | }                           |
| 201. Meadow Sweet. By H. Stevens.  |                             |
| 212. Frost and Sunshine. By Mrs. Main.   | }                           |
| 229. Direct Portraits taken in a Room. By J. Harold Roller.                      |                             |
| 243. Portrait. By W. M. Warneuke.  | }                           |
| 250. "Break, break, break, At the foot of thy crags, O sea!"<br>Elliott and Son. |                             |
| 404. Specimen of Work with Dallmeyer's Telephoto Lens. F. Boissonnais.           | }                           |
| 418. Young England. Autotype Co.   |                             |
| 637. Twelve Lantern Slides. E. G. Lee.   | }                           |
| 692. Standard Lens Flanges. Taylor, Taylor, and Hobson.                          |                             |

It will be noted that an unusually large number of medals have been awarded, and many well-known names figure as prize winners. As we shall comment upon the principal pictures as far as possible, we need make no further remarks at this point.

#### THE APPARATUS SECTION.

THE CARLOTYPE COMPANY, of Rainham, Essex, are showing specimens of work on their Carlotype cards, which are ordinary mounts rendered impervious to water and coated with a bromide film for contact printing or enlarging. They have also some very fine examples of printing on mezzotype paper, which is a rough-surfaced drawing paper sensitised for printing out.

J. D. ENGLAND, of 21 to 24, Charles Street, Royal Crescent, Notting Hill, has some exquisite negatives on celluloid films, which are absolutely faultless as regards the support. To render the use of these easy in ordinary dark slides, Mr. England also shows some of his film carriers constructed of Willesden paper or stout cards, with metal rims at the end to hold the film flat. These are exceptionally light and by no means dear.

J. W. McLELLAN, of 36, St. Paul's Road, N., shows some very fine stereoscopic transparencies, some of them of quite new subjects.

W. WATSON AND SONS, of 313, High Holborn, have an improved form of studio camera with axial swing back, side swing, and special repeating back and dark slides, the largest of which is fitted with a jalousie shutter, which is perfection of workmanship. They have also some specimens of their well-known "Acme" and "Premier" cameras with aluminium fittings. The most striking novelty is their studio stand, made of mahogany of solid construction, and so arranged that every movement can be effected from the back. Special arrangements are made for moving the front or back up and down independently of one another or together, and by merely turning over a lever the stand is immediately fixed at the desired spot, or another turn allows it to run smoothly on castors, whilst two milled screws enable it to be levelled on uneven floors.

"NAMEIT," of 44, Snow Hill, E.C., have complete founts of this useful invention for naming negatives and prints, showing specimens of titles done with the same.

W. SANDERS, of 91, Mount Pleasant, Liverpool, is showing a combined field glass and detective camera, which enables any object to be followed with the absolute certainty of getting just what one requires. It is fitted with a roll-holder, and may be used as a field, opera, marine, or night glass as desired, besides its photographic uses. We were informed that improvements are in course of being carried out which will considerably lessen the weight, which is at present rather great.

H. CROUCH, LTD., of 66, Barbican, E.C., have an exhibit of the Crouch-Dresser hand-camera, which was noticed in our columns of last week.

J. H. SMITH, of Nelson House, Stroud, Gloucester, has an adjustable vignetting frame possessing several new features, and which strikes us as being a thoroughly practical article.

H. COOPER (Morley and Cooper), of 70, Upper Street, Islington, N., shows a half-plate long-extension camera, with aluminium fittings, which is also adjustable for use with lenses of short focus, the back sliding forward towards the front. The dark slides are fitted with

patent spring locks. The whole is well made and would form a very efficient set for any amateur.

SMITH AND SON, of 102, Parade, Leamington, exhibit their plate washer, the special features of which are that the films are placed face downwards, and the tank is emptied once in every five minutes, thus ensuring complete elimination of the hypo in a very short time.

A. J. SMITH AND CO., of 18a, Clouesley Square, Islington, N., show dark slides fitted with their patent shutter springs, which effectually prevent the accidental opening of the slides.

W. GOODE, of Thorne Lodge, Mulgrave Road, Sutton, has a very convenient self-adjusting tripod head.

NEWTON AND CO., of 3, Fleet Street, E.C., exhibit two oak stands fitted with Elmer's new levelling head constructed of aluminium, and also an aluminium stand complete, which is very light. Elmer's new head, which is something similar in action to a ball and socket, allows the camera to be levelled most accurately without shifting of the legs.

J. R. GOTZ, of 19, Buckingham Street, Strand, has a very good show of shutters, both for stereo and ordinary working, all of which are constructed of metal, and work very smoothly and well. Besides these, one of his patent central swing cameras with aluminium fittings. Gotz's changing box for films, which carries two or three dozen, and in which changing could be done in daylight, is well worth the attention of all film workers; it is easy in action and by no means heavy. Mr. Gotz also shows single and double slides, and an Atlas tripod with turntable in aluminium.

GEO. HOUGHTON AND SON, of 89, High Holborn, E.C., exhibit three of their well-known Shuttle hand-cameras, and work done by the same. An interchangeable leaf album and a revolving vignetter, a table on which printing frames are placed, and the whole then revolves by clockwork, ensuring evenness of vignetting. Houghton's Photo-chromosome also attracted a good deal of attention. In appearance this is like a retouching desk, and prints, cut out in outline, and rendered translucent, are placed on the sloping desk and by means of suitable reflectors placed behind, which can be manipulated by cords, some charming results are obtained. This firm has also a very good field camera, the "Holborn," of good workmanship, light, and rigid.

ARCHER AND SONS, of 43, Lord Street, Liverpool, show one of their Ideal optical lanterns, with interchangeable lenses and celluloid dissolver, which, whilst it never actually darkens the screen, gives the effect of dissolving and automatically changes the slides.

ADAMS AND CO., of 81, Aldersgate Street, and Charing Cross Road, W.C., are showing a whole series of their hand-cameras—the Adams, Ideal, Vesta, and Hat, besides an aluminium Club camera, patent changing boxes, adjustable shutter, and lightning stand. All these are enclosed in a glass case, on the top of which are three of their Pantoscopes for viewing lantern-slides.

R. AND J. BECK, of 68, Cornhill, E.C., have a very fine show of their Autograph lenses in brass and aluminium, as well as the new detective lens which they are placing on the market. The Frena hand-camera, and results obtained by it, are well to the front, and the small and large working models of the changing apparatus attracted a good deal of attention. The Bynoe metal printing frame and celluloid well dishes complete this firm's exhibit.

TAYLOR, TAYLOR, AND HOBSON, of Slate Street Works, Leicester, have a complete set of their standard lens flanges, and this is the only apparatus exhibit which gains a medal.

J. SWIFT AND SON, of 81, Tottenham Court Road, have a case full of their famous Paragon lenses, both in brass and aluminium fittings.

#### THE PICTURES.

The time mark in the Photographic calendar for 1892 has been reached. The last Saturday in September, immutably fixed—like the laws of the Medes and Persians—for the opening *conversazione*, and looked forward to so eagerly by those interested in the advancement of photography, has come and gone, and the doors of the gallery at Pall Mall are once more open to the general public. Time was when outside the Photographic Society itself little interest was excited by this event, and the *Times* only occasionally took the trouble to review the Exhibition, whilst among the rest of the daily papers only a few gave notices, and these frequently of the briefest character. For many years past, however, all this has been changed. The amateur is omnipresent, and there are few well-to-do families where, through the distinguished photographic performances of at least one member of the household, there is not a strong and special interest in the great event of the year.

This year the interest is strongly accentuated by rumours of various kinds. Among others, that, through differences arising out of the Exhibition last year, there would be, as in Paris, two salons, and that as a natural consequence the one in Pall Mall would be considerably weakened. On looking round the walls of the gallery one sees with regret that the work of many distinguished workers is conspicuous by its absence, but it must be frankly admitted that, in spite of this much to be regretted circumstance, the Exhibition is fully up to the standard of last year.

The walls are not nearly so crowded with pictures, and there is no necessity to go on hands and knees in order to see the unfortunates which were in former years degraded to the floor level, for this year there is only one row below the line of honour. In spite, however, of the limited number of photographs, there are still far too many totally wanting in interest, and with no merit to warrant their appearance on the walls of even a local show of photographs, and still less so on those of the representative exhibition of the year.

There are only two screens, and therefore the principal wall is much more open to view. The rostrum for the lantern is a great eye-sore, and makes one end wall a most unenviable position for pictures.

In entering the gallery the eye is met by a picture so monstrous in proportion that it appears to crowd all the other pictures away in every direction. To still further increase this defect, small pictures have been placed in its immediate vicinity; and, to crown all, the crude blue-green colour of this colossal production, with its heavy dark frame, kills all the other pictures on the main wall of the gallery. The first impression of them is that they are faint and washed out, and it is only after a closer inspection that anything like justice can be done to them. This very conspicuous picture is a wave study, and not a word can be said against the original negative from which this immense enlargement (7 ft. long) has been made. It is probably one of the finest of its kind, and Mr. Birt Acres is to be complimented for his determination and pluck, for only this and the artistic eye to see the happy moment for the instantaneous shot could make such a success possible. Let anyone who may doubt the truth of this attempt to place his camera on slippery rocks with a gale blowing great guns, and the sea spray every moment dimming the brightness of his lens, and he will soon find his convictions put in the right place. When all this has been said, however, the enlargement is so out of proportion to all the other pictures in the Exhibition, that in justice to them it should have been placed on an easel by itself. Of course, it will be considered by the general public the picture of the year, for they will not find out that this immense size is secured by making it in four pieces and joining it up afterwards.

We are compelled to say so much about this picture because it is so misleading, and, striking as it is, its exhibition does not tend in any way to the advancement of the art side of photography.

Whilst on this subject, has not the time come when the whole question of frames and mounts should be taken in hand and seriously considered? It is true that on walking round the gallery one must admit that examples of eccentricity or vulgarity in framing are fewer than in many past years, and that the hanging committee have insisted upon covering up any vulgar labels that take the form of advertisements; still there are many pictures that injure their neighbours by the crude colour of their mounts. Now that bromide, platinum, and carbon are so much to the front, a more uniform system of mounting might be adopted with great advantage. Let anyone interested in this important question examine the pictures of Cembrano and Gale, and they will see that these productions do not owe their artistic effect to any trick in either mounting or framing. A lesson might be taken from the Water Colour Society. In the winter exhibition, devoted mainly if not entirely to sketches, plain white mounts are only used, but at the exhibition of the finished work, in the summer, nothing but gold mount or flat is permitted as the boundary of the picture. By the enforcement of these regulations a uniform effect is secured, and no man has power to overwhelm his neighbour.

The medals on the whole have been awarded with discrimination.

The one for the snow scene is perhaps open to question. The work is admirable, but it is neither better nor worse than that of last year, for which a similar award was given. It has to be remembered also that snow pictures taken in the abnormally clear air of the Engadine present no real difficulties to any one living on the spot, and the fair worker is evidently a resident in that health-giving retreat.

The judges have been far more liberal than those of last year. That being the case it is puzzling to understand why it is that whilst a medal has been given to above-named pictures that present no feature of novelty, and another to a certainly beautiful study of still life, but still not seriously taxing the artistic faculty of the worker, the strikingly original artistic production of Mr. Lord has been overlooked. This is a picture that would do honour to any monochrome exhibition. The subject is simple and homely—only a couple of countrymen enjoying themselves in the taproom of some village inn. There is no posing whatever, for the figures are as natural as life. The ale-house high-backed settle makes the main part of the background, and a table is before the rustics, on which is placed the earthen white and blue pint mug, and it stands out with wonderful reality, that one is inclined to take it up to see if it is empty or not. One countryman has passed his snuff-box to the other, and his face shows that he is eagerly awaiting a reply to his question, "How's that?" The other, however, is too busy with his

pinch of snuff, and enjoying it far too much to give an immediate answer. Here is a picture so well thought out, and so well carried out in every particular, that it might easily be mistaken for a photographure from the work of Gussow, and yet it has escaped an award.

The walls are not at all crowded with pictures, and report says that upwards of 200 have been rejected. There are, however, a large number of excellent pictures in portfolios which should not be overlooked by the visitor to Pall Mall. The pictures will be dealt with in detail next week.

During the course of the Exhibition there will be displays by means of the Optical Lantern, every Monday, Wednesday, and Saturday evening, as below:—

Sat.,	October 1.	Slides by Mr. W. D. WELFORD, entitled "Hand-Camera Work."
Mon.,	" 3.	Slides sent to the Exhibition for Competition.
Wed.,	" 5.	Slides by Commander C. E. GLADSTONE, R.N.; also a series entitled "Street Cries," by Mr. E. SCAMELL.
Sat.,	" 8.	AMATEUR PHOTOGRAPHER Prize Medal Slides, 1892.
Mon.,	" 10.	Slides by Mr. W. ENGLAND.
Wed.,	" 12.	" Mr. T. M. BROWNRIFF.
Sat.,	" 15.	" Mr. H. LITTLE.
Mon.,	" 17.	" Members of the Photographic Club.
Wed.,	" 19.	" " Manchester Photographic Society.
Sat.,	" 22.	Slides by Members of the Newcastle Photographic Society.
Mon.,	" 24.	Slides by Mr. A. R. DRESSER, from Photographs at the "Wild West Show."
Wed.,	" 26.	Slides by Members of the Convention.
Sat.,	" 29.	Slides by Members of the Birmingham Photographic Society.
Mon.,	" 31.	Slides by Mr. E. G. LEE.
Wed.,	Nov. 2.	Slides by Mr. E. G. LEE, Amateur Photographers' Field Club.
Sat.,	" 5.	Slides by Mr. RICHARD KEENE.
Mon.,	" 7.	— (To be announced later on).
Wed.,	" 9.	Slides by Mr. B. G. WILKINSON.

#### HOVE CAMERA CLUB.

THE first annual exhibition was held in the Town Hall on Wednesday and Thursday last, September 21st and 22nd. It was held as a section of the exhibition of the Hove Industrial Society. Four years ago this section was started with small money prizes. Last year six medals were offered for competition. This year seven more medals were added by the Camera Club, and a small committee of the latter carried out the arrangements.

The room was tastefully decorated with Indian and Liberty fabrics, palms, etc., and though large enough for the exhibits was not large enough for the number of people who crowded in, especially in the evenings. Next year it is proposed to devote to this section a room about three times the size. The photographs were hung round the room, and upon an inverted V-shaped erection running down the middle. The lantern slides were shown upon two tables in front of the windows. They were made to stand at an angle, with white card at the back, and showed in that way very well indeed. There was also a Tylar's Lanternscope for those who wished to view them more closely.

APPARATUS.—A Noakes's triple lantern, by Mr. Levett; Davenport's Ever-ready dark-room, from the makers; four Thornton-Pickard shutters, from the makers; "Frena" hand-camera, Messrs. R. and J. Beck; two "Talmers" and the "Economic," by Messrs. Talbot and Eamer; Cantilever enlarging apparatus, Mr. Hume; and a general exhibit by Mr. J. Williamson. An attractive feature was an exhibit of prize photographs lent by the Editor of the AMATEUR PHOTOGRAPHER, Mr. S. Francis Clarke's "Seven Ages" attracting much attention.

Mr. A. Pringle and Mr. J. Traill Taylor acted as judges. The quality of work sent in was rather above the average for a local show, especially in the lantern-slide classes. The latter were shown in the large room of the Town Hall on Monday evening, September 26th. The following are the awards made by the judges:—

- P 1. SIX LANDSCAPES.—Silver Medal, C. Job, Hove; Bronze Medal, A. H. Webling, Hove; Certificate, A. H. C. Corder, Brighton.
- P 2. SIX MARINE SUBJECTS.—Silver Medal, A. H. Webling, Hove; Bronze Medal, C. Job, Hove; Certificate, E. J. Bedford, Lewes.
- P 3. SIX PORTRAITS OR FIGURES.—Silver Medal, J. Hunter-Graham, Brighton; Bronze Medal, Mrs. Grant Watson, Godalming; Certificate, Miss Hall, Hove.

- P 4. SIX SLIDES, LANDSCAPES OR SEASCAPES.—Silver Medal, C. Job, Hove; Certificate, J. Williamson, Hove.
- P 5. SIX SLIDES FROM HAND-CAMERA NEGATIVES.—Bronze Medal, Major Lysaght, Queenstown; Certificate, A. H. Webbing, Hove.
- P 6. SIX SLIDES, ARCHITECTURE.—Bronze Medal, C. H. Oakden, East Dulwich; Certificate, E. J. Bedford, Lewes.
- P 7. SIX SLIDES, BRIGHTON VIEWS.—Bronze Medal, A. H. Webbing, Hove; Certificate, J. Williamson, Hove.

## Harmonising Negatives.

(Continued from page 176.)

I WILL now pass round some prints from negatives before and after rehalogenisation, calling your attention to variations in and additions to the process necessary to secure different effects. I have, with one or two exceptions, printed in platinotype as being less suited to harsh negatives than print-out silver paper, and in order to show what the process is capable of, most of the prints are from what would be considered hopelessly harsh negatives previous to treatment. I need scarcely say that I would not recommend that time should be spent, except for practice, upon any but negatives that are likely to give good results.

The prints marked A are from a portrait negative taken under very unfavourable circumstances. In the first print the deepest shadows are reversed, and the letterpress on the book is barely visible. The second print is from the negative after rehalogenisation. You will note that detail is visible in the darkest shadows, and that the light half-tone is just as discernible, the whole print being fairly soft. The third was printed after the book and hands had been locally reduced; a little more detail is visible in them, but the reduction has not been evenly performed.

B is another portrait; you will see how dark it has been necessary to print the shadows before the detail in the face was strong enough. The second print is rather too dark, but you will note the absence of the aggressive brilliancy noticeable in the first.

C is from the negative of a waterfall, lent to me by a member of our Society. In the first print the rocks are a mass of black, with one or two white leaves, showing the water as a mass of white broken only by a few dark streaks of shadow. The print, after rehalogenisation, is, I think, quite a passable picture. It was, of course, impossible to obtain detail in the seething waters, as the exposure given had been too long to secure that.

D and E are attempts to obtain passable prints from much under-exposed negatives. Both seemed to be void of detail in the shadows. The only deposit of silver seemed to be in the sky and its reflections through the trees from the water. The other portions of the negatives were badly fogged in forcing the development. D was cleared with hypo and ferricyanide, rehalogenised to soften extreme contrast sufficiently to permit of intensification, intensified with pyro and silver, and badly stained in the process. In attempting to clear this away the film frilled, and further manipulation was impossible. A slight improvement is noticeable in the second print. The surface fog was cleared away from E with bichromate and sulphuric acid before the first print was taken. It was then rehalogenised, the sky being reduced to a mere yellow stain. When laid on a sheet of white paper faint signs of detail were discernible in other parts of the plate. It was then five times intensified with mercury, followed by ferrous-oxalate (Mr. Chapman Jones's method). The traces of halation round the tree tops visible in the first print, though apparently removed by rehalogenisation, were strengthened by intensification, but the shadow detail was much improved.

If the subject were worth the trouble, I believe it would be possible to remove the halation and slight traces of fog still remaining, and to obtain a soft clear print, showing sufficient detail in the shadows.

F is a print of a pine tree avenue, from a negative lent to me. The topmost branches are invisible from halation, and the foliage in places has the appearance of being powdered with snow. The negative was rehalogenised, and I think you will admit that the second print shows these faults entirely removed.

G is a portrait group by one of our members. He performed the process of rehalogenisation from the formula I gave him. Although the first print is a warm-toned gelatino-chloride of silver, one which favours the harsh negative, I think the second

print in platinotype shows the negative to have been much improved.

H is from a negative lent to me. It is a drawing-room seen through folding doors, taken to test a wide-angle lens. The lace curtains over the window opposite the lens are badly halated. I hoped that after rehalogenisation some detail would have been seen in the halated parts. Unfortunately, the plate was poor in silver, and unable to register the extreme contrasts of light and shade. In the second print the window is a patch of light grey, void of detail, although the other parts of the print are much improved. I thought I saw slight signs of detail in the window part of the negative, and carefully reduced it with bichromate and sulphuric acid, in the hope of accentuating the shadows there, but the third print shows no improvement in that respect.

I is a view on the Brent—an attempt to show what might be done with a fairly good negative. The first print shows a blank sky. The landscape is, perhaps, a trifle wanting in brilliancy. As there were clouds shown in the negative, it was rehalogenised.

In the second print the sky and clouds print out, but the whole print is poor and flat, the result of too compressed a scale. The negative was then intensified with pyro and silver, and the third print shows sufficient brilliancy—more certainly than the first—and yet the sky, with its fleecy clouds, prints out. This is an instance of two scales being introduced into the composition, each of them being compressed slightly in the shadows, and the light half-tone rendered a little more fully.

In order to judge of what the process is capable of doing, it may be well to consider the action that takes place.

If we were to strip the gelatine film forming the negative from the glass support, and reverse it so as to have what was originally the back of the plate outwards, and were able to remove the gelatine, leaving the silver image intact, we should find that image in the form of a low relief, the shadows being extremely thin, and the high lights the thickness of the film. If now it were possible to take a shaving off the top of the image, removing only a portion of the lights and light half-tone, that light half-tone would be reduced in density, but would print as a flat, grey tone, without gradation. This is approximately what takes place when the development, after rehalogenisation, is stopped before the high lights are developed right through to the plate.

Fortunately, the simile does not hold good to the full extent. The developer in soaking downwards does not act in rigid planes. Before the shadow detail is fully developed, the action has proceeded a little further in the half-tone, and by the time the half-tone is thoroughly developed the highest lights are beginning to show traces of action at their points of greatest density. The result is that if the development be then stopped in fixation, a thin film of silver is removed from the back of the negative, thickest from the high lights, thinner from the half-tone, and not at all from the shadow detail. Some gradation of tone is therefore preserved in the light half-tone, but it must be borne in mind that this will not show the brilliancy it had in the original state of the negative.

I believe that the composition of the developer will modify the action to a slight extent. By using a little bromide, or reducing the quantity of ammonia, the action will be retarded, and the developer will act more evenly through the thickness of the film. This is the method to be employed when the contrasts are great and the shadow detail fairly strong. When the negative is thin, but still strong in contrast, the opposite method should be followed. The developer should act speedily, as by the time the shadow detail is thoroughly developed, the high lights will also have been developed so far that little or no improvement will have been effected.

You will see that in asking you to give this process a trial I do not recommend it as a panacea for all the ills that photographic negatives are heir to, nor do I suggest that in all cases where it may prove useful it will effect the whole of the cure. It must be used with judgment, and in many cases must be preceded and followed by other treatment. I recommend it as probably the best way of lowering the light in a broad and even manner, without affecting the shadows, thus introducing a second scale of light and shade into the negative.

Should the negative be too flat after treatment, it may be intensified either generally or locally to give the desired brilliancy. Or if the negative, though flat, be still fairly dense all over, it may be reduced generally or locally.

The effect of intensification and reduction will be very different, though an unobservant eye might not distinguish between them, but the worker who desires to achieve certain results will discriminate in their use.

Intensification affects the shadows but slightly, the half-tones and lights being greatly strengthened, the result being analogous to the artist's method of rendering the lights in an approximation to the natural scale and compressing the shadows.

Reduction will affect the lights to a trifling extent, while greatly altering the shadows. In the print the shadows will approach more nearly to nature, and the lights will remain flat.

The art side of the question forms no part of my subject. The application of these methods to our work in accordance with the canons of art will, I hope, be treated by a member of our society more capable than myself, at no distant date.

I may, however, to illustrate my point, call your attention to a collodion negative (which has been lent to me) made from a steel-plate engraving. If we disregard the fact that it is composed of lines, and consider only the relative values of the light and shade, we shall be struck first with the shortness of the register, the general flatness, if I may use the term, and secondly by the brilliancy of the local contrasts.

Were we to expose a thickly-coated isochromatic plate upon such a scene, using a yellow screen, we should find upon development that while the landscape portion of the negative would resemble to some extent the negative before you, the sky and its reflections in the water would, while showing strong local contrasts, be so opaque that it would be impossible to print them out; yet by rehalogenisation, followed by partial or general intensification or reduction, or by a judicious use of both, something approaching the desired result might be obtained.

As evidence of this, I will ask you to examine the negative from which the prints marked were taken.

Without presuming to compare that negative to the collodion negative, either in artistic composition or technical excellence, yet I think that the relative values of the masses of light and shade, and the local contrasts, will be found to be somewhat similar.

In conclusion I desire to express my opinion that our best negatives from a technical point of view are those which most require and will best repay the time spent in trying by the various means in our power to make the tones and relative values of light and shadows more nearly approach the results obtained by the draughtsman and the painter.

## Societies' Meetings.

**Birmingham.**—Ordinary meeting held on the 22nd inst., Mr. W. B. Osborn in the chair. The minutes of the previous meeting were read and confirmed. Two new members were nominated for election. The Chairman announced that the society was greatly indebted to Messrs. Morgan and Kidd, who had generously presented a magnificent bromide enlargement of a portrait of the President (Sir J. B. Stone). The enlargement, which was made from a negative taken by Mr. Harold Baker, forms a conspicuous feature on the walls of the club-room. Mr. Geo. A. Thomason then delivered a paper on "Stereoscopic Photography," which will appear next week. A discussion followed, in which the Chairman and Messrs. Griffiths, Iliff, A. J. Leeson, Owen, T. Taylor, E. Underwood, Watson, and E. Wilkes took part.

**Brechin.**—The annual meeting was held on the 21st inst. In the absence of the President, Mr. A. R. McLean Murray occupied the chair. The usual reports of the Secretary, Treasurer, and Curator were submitted and approved of. The Treasurer showed a balance in favour of the Society, and intimated that the debt incurred by the fitting up of the rooms had now been wiped out. The Curator showed that the lantern had been well taken advantage of during the last winter, having been borrowed by members on twenty-two occasions. The following office-bearers were elected for the coming year:—President, Wm. Shaw Adamson, jun., of Careston; Vice-Presidents, H. Braid and Bailie Lawrence; Treasurer, A. Innes; Curator, J. C. Middleton; Secretary, James D. Ross, 6, High Street, Brechin, N.B. Committee: Messrs. G. F. Robertson, B.Sc., J. Buchanan, and A. Brown. The Association having been engaged during the past year in preparing slides to illustrate linen manufacture, those ready were exhibited to the members. There were present: Bailie Simpson, Messrs. J. H. Lamb, John Lamb, G. A. Scott, D. Duke, J. Watson, Martin Lamb, J. S. Baxter, J. Bruce, J.

Cuthbert, and others engaged in this manufacture, and all expressed the opinion that the slides were very satisfactory. It is intended to have a lecture prepared to accompany them, when the Association will be prepared to circulate them among those interested in this subject. It was intimated that at next meeting the Secretary would give a demonstration of "Enlarging on Eastman Bromide Paper."

**Brixton and Clapham.**—A meeting was held on 20th inst., Dr. Reynolds (President) in the chair. The subject for the evening was "Exposure and Development," the discussion on which was to have been opened by Mr. W. Bevins, in whose unavoidable absence Mr. J. A. Butler read a short paper, addressed principally to beginners, for whose benefit the meeting was chiefly intended. Referring to exposure, Mr. Butler said that this necessarily depended largely upon the aperture of the diaphragm used with the lens, and explained that in order to form any correct idea upon the subject it was necessary to ascertain the ratio of the aperture to the solar focus of the lens. In order to avoid complications, he advised the use of two stops only,  $f/16$  and  $f/32$ , the former to be used when a short exposure was necessary, and the latter when time was no object. If this plan was adopted, and one kind of plate only used, he said a sufficiently correct judgment of exposure was rapidly and easily acquired. Besides the aperture of the diaphragm used, exposure was influenced by the distance, colour, and degree of illumination of the subject it was desired to photograph, and the sensitiveness of the plate. The degree of illumination could be estimated by observing the height of the sun above the horizon and the state of the atmosphere. He advised that a full exposure should be given whenever possible, as it was only when this was the case that any control whatever could be maintained over the character of the negative during development, and said that the amount of latitude in exposure possible with plates of good quality was very great indeed, assuming careful development. For the developer Mr. Butler recommended the use of pyrogallol, potassium bromide, and ammonia in 10 per cent. solutions, and said that pyro could be preserved in solution for an indefinite period by the use of either potassium metabisulphite ( $\frac{1}{2}$  oz. to 1 oz. pyro), or sodium sulphite (4 oz. to 1 oz. pyro, acidified with strong sulphurous acid). The character of the negative varied as development was allowed to proceed quickly or slowly. Rapid development gave a soft or even flat negative, slow development a vigorous or even hard one. Mr. Butler recommended the acid fixing bath, which could be made by adding a small quantity of bisulphite of sodium or metabisulphite of potassium to the ordinary solution of hypo. Some discussion followed, in which many points of interest in development were touched upon, and on the motion of the Chairman the usual vote of thanks was passed to Mr. Butler. It was announced that the winter session would commence on Tuesday, the 4th October, and that meetings would be held on the first and third Tuesdays in each month. The dates for the annual exhibition of the Club were fixed for the 17th, 18th, and 19th November.

**Burnley.**—On 21st inst. this society held a musical and artistic social gathering in their rooms, Hargreaves Street, when nearly seventy persons were present. During the evening a very interesting ceremony took place in the presentation to Messrs. Lee and Kellett of two medals (a silver and bronze) suitably inscribed for excellence of work in the local competitions. The rooms were beautifully decorated, and suitable refreshments were also provided.

**Cromwell.**—The monthly meeting was held on 12th inst., Mr. H. Pechey in the chair. The Secretary placed upon the table a number of packets of the Ilford printing-out paper which had been sent to him by the Britannia Works Company for distribution amongst the members of the club. He also produced for the inspection of the members several prints made by himself upon sheets of the paper that were enclosed in one of the packets, remarking that the toning of the prints was carried out strictly in accordance with the instructions (also enclosed). The members were very pleased with the quality of the prints, and eagerly sought for a packet, that they might try samples for themselves. A letter was received from the Thornton-Pickard Company, asking for a list of the members' names and addresses, and it was resolved that their request be granted.

**Croydon (Camera Club).**—Probably the last this season of the series of field excursions was held on 17th inst., when the Vice-President of the club, Mr. B. Gay Wilkinson, conducted a party of members to Lingfield. Here during the morning he gave his followers some interesting object lessons in practical composition, the method pursued by him being to choose a subject, and then proceed to show how it may be best illustrated. In this way "thumb-bit lunch" and "ploughland work" were successfully attacked, Mr. Wilkinson arranging the positions of the chief figures, and indicating the most advantageous points of view, at the same time explaining the why and wherefore. The afternoon was similarly spent at Pain's Hill and district, a promising series of scenes depicting "Gathering," and "Cottage Life," being obtained. The usual fortnightly Monday evening meetings begin on October 3rd, and an unusually interesting season is being looked forward to with much pleasurable anticipation.

**Eastbourne.**—An ordinary meeting was held on 21st inst. The President (the Rev. H. G. Jameson) occupied the chair, and among others present were Mr. H. Michell Whitley, Mr. B. Fox-Watkins, Dr. Gabbett, Dr. McQueen, and Messrs. Arnold, Arrowsmith, East, Kelsey, T. E. V. Kirtlan, Nash, Pennington, Rodda, Strange, Sparrow, Williams, E. Burnham (Hon. Secretary), and about thirty others. Seven new members, including the Mayor (Alderman W. E. Morrison), were proposed. Dr. McQueen then gave his promised "Holiday Notes," illustrated with lantern slides. The notes consisted of a description of a tour in Scotland during July, among the places visited being Oban and Dumfries (the doctor's birthplace). The slides showed great taste in choice of subject, and were wonderfully fine views of the places visited. The oxy-hydrogen light was lent and worked by Mr. Sparrow, of Pevensey Road. The next meeting will be held on October 5th, when some experiments in flashlight photography will be conducted by Mr. Flatman.

**Faversham.**—The usual monthly meeting was held on September 20th, Dr. C. J. Evers in the chair. Attendance, ten. The enlarging apparatus purchased by the Society (Lancaster's Combination Mulum-in-parvo 12 by 10 size) was inspected, and Dr. Evers showed specimens of work done with it. Several members brought photographs taken at the last excursion, which were duly criticised, and selections made for the Society's albums. Arrangements were made for a special meeting to be held on October 7th, to meet Mr. Baldwin, of the Eastman Company. The winter programme was then discussed, and the following adopted:—October 18th, "Lantern-slide Making," different processes by several members; November 15th, "Stereoscopic Photography," Dr. Evers; December 20th, exhibition of members' lantern-slides, Mr. Jackman; 1893, January 17th, "Platinotype Printing," Mr. Cremer; February 21st, "Lantern Experiments," Mr. Stunt; March 21st, "Isochromatic Photography," Dr. Evers. Notice of exhibitions of the Bedford and Leytonstone Camera Clubs were read, and circulars from Messrs. Beck and Sharp and Hitchmough were laid upon the table.

**Hackney.**—On 20th, Mr. F. Houghton in the chair, Mr. B. Wire was nominated. The particulars of the last excursion of the season, to Hampstead, were given. A tea and smoking-concert at the "Bull and Bush" was decided on. Mr. A. Barker showed prints he had executed with amidol on bromide paper. Mr. Carpenter showed some lantern plates he had made with it, also a print; he had obtained a good platinum print with it. Other work was shown by Messrs. Pollard, Gosling, Dean, etc. The Developan Company then showed their speciality. Mr. Dando was afraid the top glass (light) was not safe, but was informed that as it was not directly exposed to the light there was little danger of fog. In answer to questions from the Hon. Secretary respecting the suction of plate, it was said to be an advantage. Mr. Nunn then had the developan handed to him for trial, and report next meeting. Mr. Carpenter showed a brown-paper dark-back. Some discussion ensued respecting the limit of attendances for competing in the exhibition, in which Messrs. Gosling, Beckett, Dean, Wesson, Barton, Dando, and others took part. Meetings are held every Tuesday at 206, Mare Street, not Morley Hall as heretofore; and the Hon. Secretary's address is now 12, King Edward Road, N.E.

**Holborn.**—On the 17th inst., Mr. J. Stevens in the chair, Mr. F. C. D. Beacham demonstrated the use of his patented pigments for spotting and retouching, and his liquid water-colours for tinting photographs. With regard to the former, the pigments are put up in various forms—in crayons, cakes, or liquid. Any of them answer well for retouching purposes, and can be used upon the bare negative without either varnish or medium. For spotting prints, the cake or liquid is used, and can be applied either before or after enamelling or burnishing. It can also be used dry for spotting platinotypes or bromides, and any other papers with a matt surface. Mr. Beacham also tinted some silver prints with his liquid water-colours, and a very satisfactory result was obtained. It seemed to be a very simple process indeed, and if we cannot get photography in natural colours we can tint our photographs afterwards, and get something very near approaching it. On Friday, the 23rd inst., quite a large number of members' slides were thrown on the screen. The first were by Mr. F. J. Cobb, and among them were some of the Southern Counties Cyclists' Camp at Dorking this year, followed by some of Amersham and Chenies. Some by Mr. T. O. Dear followed, mostly slides of the Cyclists' Camp, and then a large number by Mr. J. H. Avery. Some of these were excellent slides, and included some of the upper Thames scenery, inland scenery, with a few animal studies. A small set by Mr. A. T. Elsworth, all of the Cyclists' Camp, concluded a very pleasant evening.

**Hull.**—The annual meeting was held on the 22nd inst., the President (Mr. E. H. Howlett, F.R.C.S.), in the chair. The President, in moving the adoption of the report, alluded to the successful work done by the society during the past year. Their membership had increased, and, what was more gratifying, they were financially on a sound basis. The exhibition of members' work had been the means of creating a healthy spirit of competition amongst the members,

and if was not financially quite so successful, it had artistically come fully up to their expectations. He felt that the thanks of the society were due to Messrs. Barry and Turner, who so willingly had acted as judges, and to Mr. A. N. Jameson for the gift of medals. He was especially pleased to think that it was through their instrumentality that Mr. Paul Lange had made his first appearance in Hull, and he thought that they could consider his lecture one of the most successful given in the town during the past session. The adoption of the report was seconded by Mr. Allcott, and carried *nem. con.* Numerous suggestions were made to further improve the working of the society, and mention was made of the society's affiliation with the Photographic Society of Great Britain. It was also announced that steps were being taken to secure the services as lecturers of some of the best known authorities in the art and science, it being expected that the winter syllabus will excel even that of the past year. Votes of thanks were accorded to the retiring officers and council; and, especial mention being made of the services of the President (Mr. Howlett) and the retiring Secretary (Mr. J. H. Allcott), both suitably replied. The former stated that he felt he had earned his retirement, having passed through the secretarial, vice-presidential, and presidential chairs. He assured them, however, that, though but an ordinary member of the council, his efforts would always go towards promoting the society's success. The election of council and officers was then proceeded with, the following being the result: President, Mr. C. D. Holmes; Vice-President, Mr. John Pybus; Treasurer, Mr. D. W. Sissons; Hon. Lanternist, Dr. Walker; Hon. Librarian, Mr. B. M. Stoakes; Hon. Secretaries, Messrs. A. H. White and E. E. Cohen; Council, Messrs. J. H. Allcott, H. L. Adams, C. F. Amos, G. J. Boville, Rev. Coleman, Croshaw, Rev. W. Hay-Fea, E. H. Howlett, F.R.C.S., A. N. Jameson, T. Rose, Dr. Stothard, and Dr. Hollingsworth. It was arranged to hold club meetings on Thursday and Saturday evenings, during the winter session, when papers will be read and slides exhibited.

**Liverpool (Am. Phot. Assoc.)**—On the 22nd inst. the formal opening of the beautiful new club-rooms was celebrated by an "At Home" given by the President, Mr. William Tomkinson, who gave a most humorous poetical effusion, specially written by Mr. Clarence E. Dyall. The committee of the Artists' Club, whose rooms adjoin those of the Photographic Association, very kindly lent the use of their rooms for the occasion, thus enabling the President to invite the whole of the members (upwards of 300) and their lady friends. An excellent musical programme was contributed by Miss Anyon and Messrs. Cleaver, Yates, Blenkarn, Talbot, Kelly, Anyon, Macreedy, and H. and W. Norman-Thomas. Mr. Yorke convulsed the audience with his humorous recitations. Mr. Geo. E. Thompson gave his interesting new lecture on "The Roman Campagna," illustrated by slides from negatives taken by him in the spring of this year. The lecture was listened to with great attention, frequent bursts of applause testifying to the appreciation of the crowded room. After an interval for refreshments, votes of thanks were accorded to all who had so kindly come forward to assist, and to the President for his entertainment. An impromptu dance, which was entered into with great spirit, brought a most enjoyable evening to a close.

**North London.**—On the 20th inst., Mr. A. Mackie in the chair, after the usual preliminary business, the Secretary reported that having tried the new developer, Amidol, he had found it to work very satisfactorily. In some cases, according to exposure, he had found it difficult to obtain printing density, but from the character of the image and the clearness of the shadows, after-intensification gave no trouble, and worked well. As a one-solution developer it appeared to fill the claims made for it. The Secretary further reported that he had received tickets for the annual exhibition of the Photographic Society of Great Britain, which under the affiliation rules were to be obtained by members at half price. Mr. Redmond Barrett then gave a practical demonstration of retouching, showing with regard to negatives brought by himself and by members what should not be attempted, what ought to be done, and how to do it. Scratches, pinholes, and other defects were also dealt with, and the best mode of dealing with such explained and illustrated. With regard to the use of retouching medium, Mr. Barrett advised the use, not of the finger tip, but of a tuft of cotton wool, with which a very small quantity of medium should be well worked not merely on but into the film. Should any of the work come away in the subsequent varnishing, it would have to be made good when the varnish was dry; in fact, it was generally desirable to make any finishing touches at this stage.
